These "professors" do not thrive in California or Nevada quite so well as they did formerly. Our people have acquired a large experience in mining affairs, and are not so easily duped by the reports of unscrupulous and ignorant pretenders; besides this fact there is a class of really accomplished mining engineers who entered the field fully equipped, with a thorough scientific training, and who have had since the most varied experience in our boundless mining regions. The experience and experiments of these men, both in the field and in the laboratory, have added largely to our scientific knowledge. It is likely that some of these trained engineers have made mistakes. It would be wonderful if they had not. We know it is the habit of some people to speak slightly of these trained experts as mere hook men and theorists, and to express a decided preference for what they are pleased to term "practical" men. After all science is simply the recorded result of the most intelligent practice; and the man who has learned, what has already been accomplished in a given field, has certainly a great advantage over one whose knowledge is based chiefly or altogether on his own narrow experience. Of all theorists commend us to the practical man. He can out-theorize the fullest book man of them all. We recall an incident related by Prof. Siliman while in eastern Nevada on professional business several years ago. His appearance in the camp excited great expectations, and a self-appointed committee of the over-anxious showed a disposition to take possession of him. But the shrewd gentleman eluded the thrall, and went out into the hills to see the mines and to meet the miners face to face. He spoke to a solitary miner who was working in a shallow incline, and, seated upon pieces of rock, they were soon engaged in conversation upon the mines of the district. The miner, who was a plain sensible fellow, detected the calmer of his companion, and told him bluntly that he didn't "go much on hook men; they're all theory. Give me the practical man." The professor laughed heartily, and reminded the other that, for a practical man, he had advanced more theories in less time than any man, whether scientific or practical, whom he had ever met. Quite unconsciously the miner, who affected to condemn theory, had offered theories as freely and readily as though he had been an erudite mining engineer.

A little reflection would soon dispel the prevalent opinion respecting practical and scientific men; would mark the difference between men who have been trained for a given pursuit, and those who have had no training, and are generally characterized as "self-made." Every skillful mechanic in our shops knows the value of training. One does not hear much of self-made machinists or joiners or other skilled artificers. Skill follows trained methods and practice. What would happen to the novice—the self-made man—who should engage in a contest with a trained and skillful lawyer or doctor, pugilist or wrestler, blacksmith or carpenter? Why, he would be beaten every time. We

properly lay stress upon a man's experience: how much abler is the man who, in addition to his own experience, is fortified by the best experience of the world? That is simply the difference between the so-called practical man and the disciplined expert—the man of hooks and theories. Heaven-horn experts are seen but seldom. There are remarkable men—the architects of their own fortunes—who in spite of the want of special training have achieved brilliant distinction in the highest professions. Such men pluck renown from adversity. We have in our thought the distinguished engineer who recently came to this coast, who presents a shining example of a self-made man.

Pacific Coast Fish.

At the last meeting of the California Academy of Sciences, Prof. Jordan, who is collecting data in connection with fish matters on the Pacific coast, for the U. S. census, presented to the museum a donation of 18 species of fish. He said the Commission had now about completed its labors here, and he intended soon returning East. He said, in a thorough exploration of the fish of our coast, they had obtained 270 species, of which 200 were previously known to science, 25 were known through Mr. W. N. Lockington, and about 45 new species he had discovered. He said we have 19 species of sharks on the coast, including nearly all the known varieties. Last spring he caught, in Monterey, a very enormous man-eating variety of sharks; one was taken at Soquel. Their teeth were large, and the animals are very dangerous. They measured from 23 to 24 ft. in length, and weighed full 2 tons apiece. The Professor has preserved their jaws. He said he knew of another and larger variety of shark found here, averaging 32 to 33 feet in length, and weighing three tons apiece, which had but small teeth, was quite lazy, and not at all dangerous. He then spoke of the well-defined limits of

Different Fish Systems of the Coast;
One set extending from Point Conception as far north as Monterey bay, which are very numerous, and rarely come farther north into our colder waters, although a few sometimes reach San Francisco bay. The second set extend from Monterey to Puget sound; and a third set are found wholly north from there on toward the Arctic. Monterey bay is middle ground where the fishes from north and south meet, and no locality on the Atlantic sea-coast is so rich in species. It has about 130 species, and San Francisco has the same. Santa Barbara has 95 kinds, as our rock cod and flounders do not go so far south. At San Diego there are found 80 species. The great tribe of so-called perch on our coast are, none of them, the true perch. In Puget sound they found about 90 species, all of which were northern varieties. The Fish Commission have made very thorough work of it, and left no opportunity unavailing of to make their report complete. In the Columbia river there are taken annually a million and a half of salmon fishes, averaging from 25 to 30 pounds each. In San Francisco bay there are taken and marketed annually from seven to eight million pounds of all varieties of fish. Professor Jordan gave it as his deliberate and well considered opinion, as a scientific expert, that

The Salmon of this Coast
Are in no wise inferior to any salmon caught on the Atlantic. This he says after a most elaborate and exhaustive study of the salmon along the entire coast at all seasons of the year, where they are found in a great variety of conditions. He said the red and white flesh of salmon was found in the same varieties of fish, and indicates difference of condition, and not variety of species. We have only five species of salmon on the whole extent of our coast, all included. When they are in superior condition their flesh is a deep red, and old males, as they approach the spawning age and season, finally become nearly white. They are then out of condition for eating. In the autumn they undergo certain rapid changes of condition; their form becomes distorted, their backs arched, and their whole form becomes deeper and less symmetrical, quite unlike their regular and beautiful figure in spring. Their jaws enlarge and teeth change in form and number. They run up rivers and the females spawn, after which all die. The reason of this universal death after the spawning period is not yet fully determined. Their life history, however, is: They are hatched in clear water, in the shallow streams, brooks and rivulets of the interior connecting with the ocean. They descend to the sea when three to four inches long, and after a long absence, return at about the age of four years. When they approach the coast they become attracted by the strata or currents of fresh water flowing from rivers.

When at Sea They Feed Freely and Bite Vigorously

At a hook, but as soon as they enter fresh water and mount up the rivers, they cease entirely to eat anything and therefore never take a hook. When thus caught their stomachs are always empty. As soon as they begin to fast, their features begin to become sharper, and they rapidly become what fishermen call dog-salmon. They appear then impressed with an irresistible desire to penetrate fresh water streams as nearly to their fountain-heads as possible, and follow the sources of the Columbia river as far as Montana. During this rapid

journey they distribute their spawn and keep on going until the water is so shallow they can barely crawl up stream farther; then they hatter themselves up, and in October, having spawned, all die, and none ever return to the sea. Prof. Jordan thought they died from pure exhaustion, as all become mottled or less bruised by rocks, and none have tested any food since leaving the ocean. Ventura river is the farthest south that any salmon run up rivers, as few rivers below these have any direct outlet to the sea, but run through such obstructions as sand-bars.

At Columbia river, from April to July, there are from 1,500 to 2,000 boats out salmon fishing all the time, extending from the bar clear up to off Mount Ranier, forming a perfectly impenetrable web of nets. Some adventurous fisherman, venturing too far out to sea on the bay, is drowned almost weekly in the height of the season, when the canneries are harvesting their annual fish crop.

Future Fish Supply.

Prof. Jordan was asked his opinion if such excessive fishing was likely to endanger the future supply of fish, and said that if they ceased catching salmon after July enough would ascend the river later than that to fully stock the river with the required amount of spawn necessary to keep up the usual supply, for in the matter of fish-spawn nature is very hountiful in her supplies.

The remarks were listened to with marked attention, and are of especial interest, as giving the well digested opinions of an eminent scientist on the matter of a very important item of our food supply.

The Ontario Silver Mine.

This remarkable silver mine in Utah Territory was scarcely known four years ago, and yet so valuable is its large ore body and so skillfully has it been explored and worked, that the product already exceeds \$4,000,000. A recent number of the *Salt Lake Tribune*, gives an interesting account of the Ontario, which we briefly summarize. Notwithstanding the large product of the mine, there has never been a time when more than 25 men were employed in extracting ore. The ore body is large and easily mined. The volume of water is great, indeed, it costs twice as much to take the water out of the mine that it does to extract and mill the ore. Owing to the superabundance of water the pumping machinery is both heavy and costly. The heaviest pumps in the mine are in the 500-ft. shaft. The water is hoisted from the 500-ft. level up to the 100-ft. level, where it passes out through the Union tunnel to the surface. One pump in the 600-ft. shaft also throws water to the 100-ft. level. The other small pump in the new shaft throws to the heavy pumps on the old shaft, a connection being made between the shafts. On the 700-ft. level, as soon as the station is out, a heavy Knowles pump is to be placed and is intended to do duty until the Cornish plunger is ready to take its and the other pumps places. This plunger will be in place this fall and some idea of its magnitude can be formed from the fact that it will cost, at the lowest estimate, \$150,000. It is a vast piece of machinery which lifts water from level to level, and with each motion of the plunger the water on each level is taken up to the next where it is received by tanks. It will require an engine of 150-horse power to do the work. In order to furnish steam for lifting the ore, waste and water from this great fissure, there are at the present time 12 large boilers, the largest in use in the Territory.

Experience shows that as depth is attained in the mine the ore becomes not only baser, but richer. The ore, which may be characterized as refractory, is treated at the mill—one of the most thoroughly complemented on the coast—in a highly scientific manner, and yields a good and satisfactory percentage. The mill has 40 stamps, and is easily capable of reducing 50 to 60 tons daily. This amount of ore is readily extracted, and the foreman of the underground works informed the *Tribune* correspondent that it would be an easy matter to supply an 80-stamp mill for three years from the ore already in sight. There are at the mill 3,000 tons of ore held in reserve, so that in case any mishap should occur, either to the machinery at the mine, such as a breakage of any of the pump columns, or a cave in the shaft, the mill can keep steadily at its work turning out the hullion until the necessary repairs have been made. From the outset the management of the great property has been admirable, and the shareholders of few incorporated companies have received such uninterrupted satisfaction as those of the Ontario.

COMPARATIVE HEAT OF ARIZONA.—A Tucson correspondent of the *Record-Union* has this to say of the heat in Arizona: The months of June and July are the hottest months. This year the thermometer has at no time during these months, or at any other time, risen to over 110°, according to the signal station report. Ordinarily the thermometer ranges from 85° to 100° during the warmest portions of the day. I have found no heat in the Territory as oppressive as that of Marysville and Oroville, California. The nights are cool and delicious; many persons sleep in the open air; whole families occupy the sidewalks, perfectly secure from all intrusion.

Leaf-Variation in Acacia Trees.

[Written for the Press by W. G. KERR.]

Of all the families of plants, the order of *Leguminosae* or pulse family, perhaps, stands second to none in usefulness and number of members except the *Gramineae*. Among its

vast tribes we find the most diversified forms, from the tiniest little herbs that creep along the ground to the mighty tree of this forest. Our succulent clovers give us the best fodder for our domestic animals, and peas and beans are among the strongest food for men. From the pods of the tamarinds cooling drinks in the hot countries are prepared, and from the similar fruit of carob, mosquitos and screw bean we obtain in the most arid regions food for man and beast. From the indigo and campêche tree we get our dyeing materials, and, finally, from some of the acacias we receive the best of gum, tannin, as well as the hardest of woods. But, putting aside all these direct useful properties, evident to every man, this remarkable family is of special interest to the botanist.

That those readers who are little familiar with the subject of this article, the heterophyllism* of the acacia tribe, it becomes necessary to review in short some of the characters of the pulse family. In spite of its large size, this family is what might be termed a natural one—that is, its limits are pretty well defined, though divided in three suborders—the *Papilionaceae* or pea family, the *Cesalpiniaceae* or brasilletto family, and the *Mimosaceae* or acacia family. Though each has its special characters, they are all known by the fruit, which is termed a legume or a pod that is formed by one pistil which dehisces or splits in two valves. It must, however, be remarked that there exist legumes that, owing to their peculiar development, as the screw bean, the carob, etc., do not open at all. But another feature that may be said to be one of their chief characteristics is the compound leaf. A compound leaf in its strictest sense is a leaf which has two or more distinct blades, but, as later shall be explained, we may even term a leaf with one blade compound, if it is articulated or jointed to the stalk. The bipinnate, or compound leaf, with only two leaflets, is rare. It occurs in a tropical tree named *Bauhinia*, and is foreshadowed in the common red bud or *Cercis occidentalis*. The ternate or trifoliate leaf is the familiar leaf of the clover tribe, and the beans and peas have a truly pinnate leaf. In the honey locust we have it double pinnate, and in some *Mimosae* the leaflets become so numerous that it becomes a difficult task to count them. Some leguminous plants, on the contrary, as for instance the so-called broom (*Spartium*), displays when young three foliate leaves, but later produced leaves have only one of these, and the plant becomes gradually leafless, the green stems performing their office. In various Australian plants, as for instance the *Templetonia*, a shrub with scarlet pea flowers, not uncommonly planted, there never appears more than one leaflet. In the *Parkinsonia*, a thorny shrub of southern California, we have a compound leaf which has its mid rib very much widened and the leaflets very inconspicuous, and very often drop off, seemingly, without hurting the mid ribs that remains on for a long time afterwards. I have dwelled on these, as it may perhaps seem trivial particulars, that come later idea may be better understood, and shall now pass to the direct subject of this article.

Many are familiar with the golden, blooming, fragrant acacia, planted as it is everywhere in one of its endless forms. Here it is *mollissima*, with its dark bluish foliage, or *dealbata*, covered with fine silvery bloom that, as a mighty tree, shades the house; or it is *latifolia*, with its stiff upright foliage flourishing on the poorest spot in your garden; or it is *armata*, with its little leaves and big thorns, that ought to be, if it is not, part of your hedge; or it is *verticillata*, with the sharp leaves arranged in a whorl; or it is perhaps *calamifolia* or *squamosa*, with its long needle-shaped leaves; or it is perhaps *cul-triformes*, with its trimmular, bluish foliage and slender branches hurled down with golden yellow flowers; or perhaps still another of this

vast tribe. They are all acacias; their flowers and fruit (pods) tell us; but where is the compound-leaf like in *Mollissima*, and what resemblance do these sickle, needle or triangular vertically-placed leaves bear to the fine mimosa-like leaf of the former?

No doubt you have occasionally seen planted

ever, you find a peculiar development (Fig 4); the mid rib evidently has expanded and part of the leaflets have dropped off. In the one higher up (Fig. 5) there has only two remained suspended, until, finally, in Fig. 6, you have none left, and in Fig. 7 is seen the permanent leaf-form in the blooming twig. You have now seen

in *melanoxydon* when young can be seen on the old tree. The phyllodious group of acacia are almost all Australian, and add to the peculiar charm this country has to the botanist, and they were among the strange looking plants that astonished the early discoverers and caused the name of Botany Bay. In its most remark-

able flora and fauna many naturalists have thought they found in Australia a remnant of a former period of the earth. The great botanist Sir Joseph Hooker, however, who has given the botanical part of this question a great deal of investigation, declares that he cannot find sufficient ground for the belief. But he dwells on one point that seems to speak for those views. He found by comparison that the western and eastern parts of Australia have comparatively few species in common. This is very strange, as no mountain chain separates them; but what is still more strange, western New Holland has many more genera in common with Africa than the eastern, and in the same manner the southeast has South American forms not found in the west. To meet therefore on the Isle of Bourbon, not very far from Africa (comparatively speaking) and on this side of Madagascar, with a phyllodious acacia of the peculiar Australian type, which is, as remarked, not found outside of that part of the world, is certainly very interesting; and when again we seem to find almost the same form in the Sandwich Islands, we naturally wonder

still more. There is a peculiar charm in pondering over the history of plants, hidden as it is in the dark of the past. We rejoice when finding in the grand volume of nature, pages where the letters still are plain and visible. Such a page is the *Acacia melanoxydon*, it lies open for you. Read the story which the plant relates.

You see before you the exile of another country. That world we once inhabited has almost disappeared. Where now the waves roll was once an immense continent larger than any now in existence. From India to far south in the Pacific it stretched, and from the shores of Mauritius to the Hawaiian Islands. It was the home of rich and luxuriant flora. In this immense country, dotted with large, clear lakes as those of North America, with rivers deep and swift, flourished together with beautiful trees the great tribe of acacias, mingling their delicate foliage with the feathery crown of the cycades in the halmy air. In the grassy plains, now deserts of *spinifex*†, there was an eternal spring. Huge kangaroos compared with which those of the present are but a weak progeny, found here abundance of food even to satisfy their enormous appetite. But alas, the genial climate of this region should not last. As the greater part of the continent gradually sank into the bosom of the sea, another was slowly raised and mountain chains were heaved up. The beds of rivers were changed and the beautiful clear lakes lost their affluents and filled with salt. They gradually became dry, and from their empty basin, heated by the tropical sun, the hot winds commenced to blow fury as from a furnace. Then our struggle commenced; death and disease thinned our ranks. The scorching wind and burning sun parched the delicate little leaves, and they fell to the ground, only the leafstalk remaining pointing heavenward for relief. It was in vain our innumerable flowers scattered broadcast their millions of seeds. The little plants brought forward their delicate little leaves, their inheritance from their fathers, all for naught. One by one they dropped. For a long time this continued until all but a few became leafless. Only my ancestors and nearest relations still huddled on, until at last they also had to yield to the rigor of the climate.

But as the sea expanded and surrounded the island you now call New Holland, humid breezes brought relief to the well-nigh exhausted acacia, and they felt it. Their leaves once lost they had no power to recover, but the leaf-stalks commenced to expand each in their own peculiar fashion. Some became broad and huge, like wings; others became rounded and elongated, like a pine needle, others triangular shaped; while those who, in the hard struggle, had been forced on thorns, hardly managed

† Name of grass covering immense barren regions in the interior of Australia.

HETEROPHYLLISM OR LEAF VARIATION OF, ACACIA TREES ILLUSTRATED.

in the garden or street a remarkably symmetrical acacia with straw-colored flowers and almost resembling the Monterey cypress in shape; *melanoxydon* is its name, and it is one of the most useful of its tribe. If it is a young tree, you will here receive answer to your question, in what relation the sickle-shaped vertically-

how gradually the compound leaf has developed to perfection, and how it just as gradually has emerged into a form as peculiar as that of any or all the forms I named before. Few are, however, the examples where as beautiful an illustration of the most remarkable phenomenon can be observed. In the most of the

LEAVES AND FLOWERS OF ACACIA MELANOXYDON.

placed leaves stand to the mimosa leaf. Possibly the two first leaves (Fig. 1) have dropped off. At this point all the acacias are alike. A bipinnate-compound leaf has succeeded the seed leaves; few of them ever produced more than two pairs of these. Higher up the stem you will find a more developed leaf with four divisions (Fig. 2), and still higher up you have the perfect leaf, almost like that of a mimosa or *Acacia mollissima* (Fig. 3). Close to this, how-

species the *phyllodia*, as the vertical expansions are termed, succeed almost abruptly the pinnate leaf. Only two species, so far as I know, besides *melanoxydon* display this peculiarity; the one is *heterophylla*, a native of Isle of Bourbon, an African island, and *Kau*, a very close relation, almost identical with it, found on the Sandwich Islands. These two widely-separated forms bear during all their lifetime two kinds of foliage, and this change observed

*Heterophyllism from the Greek *heteros*, various; *phyllon*, leaf.

THE INDUSTRIAL WORLD.

Enormous Grain Elevators.

So vast has become the grain trade of New York that it is the belief at the Produce Exchange that the great bulk of the shipping trade of the west will center there. They count upon six additional steamers, at least, a week, leaving that port within the next year, entirely devoted to the grain, cattle, and meat traffic between this country and Europe. To meet the demands of the grain trade, enormous elevators have been built with such facilities that as many as 40 and 50 cars can be unloaded at one time. The following facts concerning them will give some idea of the business done: The elevator built by the Erie Railroad Co., and only completed very recently, has a capacity for 1,500,000 bushels of grain, and is able to unload a car in the extremely short time of three minutes. It is situated on the New Jersey side of the North river, only a short distance from Pavonia ferry. It is claimed by the company to be the largest and most complete in construction in the country. The dock on which it stands is 1,750 ft. long, 100 ft. wide, the elevator itself being 375 ft. long, 80 ft. wide, 165 ft. high, with a stock of 180 ft. The machinery is run by two 250-horse power engines, and the elevator can receive and unload 40 cars at one time by means of steam shovels, at the rate of three minutes, and can load four ordinary steamers in four hours. The cost of the structure was \$750,000.

The immense elevator reposes upon a foundation of granite pillars 16 ft. high and 8 ft. square. The large elevator built by the Pennsylvania Railroad Co., is located at Harrison's Cove, Jersey City, and is so constructed that it will hold more grain than that of the Erie. Bulk will have to be broken only once from Chicago or St. Louis to its final destination.

Those built by the New York Central and Hudson River road, as before stated, are at 61st and 63d streets, North river. Both are capacious. The second can unload and receive a cargo at the same time. 400 cars can be unloaded in a day and 500,000 bushels shipped into vessels. Two of the largest ocean steamers can easily lie alongside the dock of the second elevator and be loaded or unloaded at the same time. The building is 355 ft. in length, 70 ft. in breadth, and 131 ft. to the ridge of the roof, with a dock on both sides and on the river front. It is built of timber laid and spiked in what is known as the crib form, and over 3,000,000 ft. of timber was employed in its construction. It has no less than 20 shipping bins, each holding 1,000 bushels of grain, and can be cleared at the rate of 7,000 bushels an hour. The cost is close upon \$500,000.

THE PULLMAN PALACE CAR CO.—One of the largest manufacturing establishments in the country is now being built by the Pullman Car Co., at a cost of \$1,000,000. It is located near Chicago, on the Illinois Central railroad, three-fourths of a mile south of the Kensington station. About 150 acres is included in the site, and will be laid out in drives and lawns, with two attractive parks. On one side is water transportation by Lake Calumet, and on the other the Illinois Central railroad tracks, while but a short distance away is the junction of the innumerable roads leading into Chicago. The structures will be of brick and stone, having 1,130 ft. of frontage and facing the double track of the Illinois Central railroad. They will consist, first, of two parallel buildings for erecting shops 690 ft. long and 87 ft. wide. The central section, containing the offices and store-rooms, will be 100 ft. long and 100 ft. deep, three stories high, with a tower rising to a height of 146 ft. In the rear of these will be a series of four buildings, covering an aggregate frontage of 1,047 ft., with a general depth of 200 ft., forming the wood machine shops, blacksmith shops, varnish-room, repair shops and two erecting shops. Still back of these will be another erecting shop, 474x86 ft., a dry kiln 150x80, and a foundry 130 ft. front and 200 ft. deep. These buildings are compactly located as regards each other, making them convenient of access. The erecting shops will have stalls for 50 passenger cars and 100 freight cars at one time. Tracks running between the various shops will be provided with numerous turn-tables, so that cars can be run in and out without switches.

The Edison telephone connects the British Parliament buildings directly with the London newspaper offices, so that the debates can be reported and put in type an hour earlier in the morning than heretofore. It was but lately that the London Times was printed on a Yankee press; now it is a Yankee that helps on the chin music in Parliament, and we half expect that they have a Yankee type printing machine connected with it, one that is claimed to set up 100 lines an hour, instead of 40 by hand labor. Really, Brother Jonathan can now help the old man considerably.

PIN MANUFACTURE.—A writer, who has been looking into the statistics of pin manufacture, makes the statement that while 50 years ago it took one man a minute to make 14 pins, to-day, with our improved automatic machinery, a single workman can make more than 1,000 in the same time.

AMERICAN WATCHES.—The American Watch Co., of Waltham, Mass., has lately received an order from the British government for 372 watches, intended for the use of conductors, engineers, station masters and other employees of the state railroads of India. This is the third large order received by the company from the same source, and, like the former ones, was obtained in public competition with foreign manufacturers. The London *Jeweler and Metal-worker*, in its issue of January 15th, observes, in reference to this order: The contract for watches to be used by the officials of the Indian state railroads has again been secured by the American Watch Co. This is the third time Messrs. Robbins & Appleton have received this distinction, which is not a barren one, for it must be evident to the most prejudiced individual that the timekeepers supplied on the previous occasions must have given satisfaction, and answered the tests required of them. This is a mortifying fact for Englishmen, especially for those who believe that were manufacturers here to show more enterprise, they would be able to compete advantageously in the manufacture of all grades of watches.

STATISTICS OF THE IRON AND STEEL INDUSTRY. Mr. James M. Swank, Secretary of the American Iron and Steel Association, has nearly ready for distribution, to members of the association, a directory of the iron and steel industry of the U. S. This compilation will give the name and location of every blast furnace, rolling mill, steel works, forge and bloomery in the country, with full information concerning each, especially with relation to the character and capacity of the same. From this valuable source of information we glean the following leading statistics: Number of completed blast furnaces, March 1, 1880, 697; number in process of construction, 44; annual capacity of completed furnaces, 13,000,000 tons. Number of completed rolling mills and steel works, 382; number now in process of construction, 10; number of puddling furnaces, 4,467; number of heating furnaces, 2,419; number of trains of rolls, 1,397; annual capacity of rolling mills for finished iron, 400,000 tons; annual capacity of rail mills for heavy rails, 2,150,000 tons; number of nail machines, 4,152; number of Bessemer steel works, 11.

RAILROAD SCALES FOR SOUTH AMERICA.—The bark *Amy A. Lane*, was recently loaded with American goods at New York, for Rio de Janeiro. An important part of her cargo is a lot of 40 large railroad scales, built by the Howe Scale Company for the Dom Pedro railroad, of Brazil. This line is one of the most important in Brazil, running from Rio into the heart of the agricultural region, and enjoys the special patronage and care of the Emperor, in whose honor it is named. The selection of the Howe scales for use on this road is a compliment to American mechanics, which should be appreciated, and shows a preference for them in that country over all others.

AMERICAN VS. ENGLISH MECHANICS.—An English manufacturer traveling in America for the purpose of inspecting various industrial establishments, recently wrote: "I spent some hours recently at the Cleveland rolling mills. They have a wire mill attached for drawing nothing but Bessemer steel wire, of which they turn out 75 tons per day, and have one room with 1,000 small hocks, each man tending 32 hocks, whereas in England we consider a man that runs eight blocks of steel is a wonder. So much for your country. I saw it with my own eyes, and was never more astonished."

THE COTTON-SPINNING INDUSTRY OF THE WORLD.—This industry, of the entire world, consists of 71,250,000 spindles, of which more than half (or 39,500,000) are operated by British manufacturers. The U. S. has 10,050,000; France has 5,000,000; Germany, 4,800,000; Russia, 2,860,000; Switzerland, 1,870,000; Austria, 1,800,000; Spain, 1,775,000; Italy, 900,000; Belgium, 800,000; India, 1,275,000; Sweden and Norway, 310,000; Holland, 230,000; and other countries, 80,000 spindles.

THE INDIA RUBBER BUSINESS.—There are in the U. S. and Europe more than 150 manufacturing of India rubber goods. These employ from 10,000 to 15,000 operatives, and consume annually about 40,000,000 lbs. raw material. The bulk of the crude rubber, and the best quality, is brought from Brazil, though considerable quantities are obtained from Central America, Africa (especially Madagascar), India and the islands of Borneo and Sumatra.

BUILDING STONE FROM FURNACE SLAG.—Building stone is manufactured from furnace slag on a large scale at Osnabruck, Germany. One establishment delivered 6,000,000 brick during the last year. The artificial stone is valuable for ventilation, as it permits four times as much air to pass as ordinary building stone; it also requires 20 times as long to saturate the stone with moisture as it does the bricks baked from clay.

AMERICAN WINDMILLS IN ENGLAND.—Windmills of American manufacture continue to be exported in considerable numbers, particularly to the British colonies. One of the largest lately shipped had a diameter of 24 ft., and single castings in it weighed 5,000 lbs.

The largest Bessemer converters at work in England are the 10-ton converters at Sir John Brown & Co.'s works.

Mining and Scientific Press Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1864—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice free. Address, **DEWEY & CO.,**
Office Mining and Scientific Press and Pacific Railroad Press, 202 Sansome Street, S. F.—1579.

- NOW READY!

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW on SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Quarto. 234 Illustrations.

By ROBERT GRIMSHAW, Ph.D., M.E.,

Member of the Jury on Wood-working Machinery at Paris Exposition of 1878.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand, saw, Mulay, jig, drag, circular, cylinder and band Saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, swaging, gumming, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 36 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copiously indexed. Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the price is this date made \$2.50, postage paid.

ROBERT GRIMSHAW,

624, 626 and 628 Market Street, Philadelphia

March 10 1880.

California Inventors

Should consult DEWEY & CO., AMERICAN PATENT SOLICITORS, for obtaining Patents and Caveats. Established in 1830. Their long experience as journalists and large practice as patent attorneys enables them to offer Pacific Coast Inventors far better service than they can obtain elsewhere. Send for free circulars of information. Office of the MINING AND SCIENTIFIC PRESS and PACIFIC RURAL PRESS, No. 202 Sansome St., San Francisco.

THE INDUSTRIAL WORLD.

Enormous Grain Elevators.

So vast has become the grain trade of New York that it is the belief at the Produce Exchange that the great bulk of the shipping trade of the west will center there. They count upon six additional steamers, at least, a week, leaving that port within the next year, entirely devoted to the grain, cattle, and meat traffic between this country and Europe. To meet the demands of the grain trade, enormous elevators have been built with such facilities that as many as 40 and 50 cars can be unloaded at one time. The following facts concerning them will give some idea of the business done: The elevator built by the Erie Railroad Co., and only completed very recently, has a capacity for 1,500,000 bushels of grain, and is able to unload a car in the extremely short time of three minutes. It is situated on the New Jersey side of the North river, only a short distance from Pavonia ferry. It is claimed by the company to be the largest and most complete in construction in the country. The dock on which it stands is 1,750 ft. long, 100 ft. wide, the elevator itself being 375 ft. long, 80 ft. wide, 165 ft. high, with a stock of 180 ft. The machinery is run by two 250-horse power engines, and the elevator can receive and unload 40 cars at one time by means of steam shovels, at the rate of three minutes, and can load four ordinary steamers in four hours. The cost of the structure was \$750,000.

The immense elevator rests upon a foundation of granite pillars 16 ft. high and 8 ft. square. The large elevator built by the Pennsylvania Railroad Co., is located at Harrison's Cove, Jersey City, and is so constructed that it will hold more grain than that of the Erie. Bulk will have to be broken only once from Chicago or St. Louis to its final destination.

Those built by the New York Central and Hudson River road, as before stated, are at 61st and 63d streets, North river. Both are capacious. The second can unload and receive a cargo at the same time. 400 cars can be unloaded in a day and 500,000 bushels shipped into vessels. Two of the largest ocean steamers can easily lie alongside the dock of the second elevator and be loaded or unloaded at the same time. The building is 355 ft. in length, 70 ft. in breadth, and 131 ft. to the ridge of the roof, with a dock on both sides and on the river front. It is built of timber laid and spiked in what is known as the crib form, and over 3,000,000 ft. of timber was employed in its construction. It has no less than 20 shipping bins, each holding 1,000 bushels of grain, and can be cleared at the rate of 7,000 bushels an hour. The cost is close upon \$500,000.

THE PULLMAN PALACE CAR CO.—One of the largest manufacturing establishments in the country is now being built by the Pullman Car Co., at a cost of \$1,000,000. It is located near Chicago, on the Illinois Central railroad, three-fourths of a mile south of the Kensington station. About 150 acres is included in the site, and will be laid out in drives and lawns, with two attractive parks. On one side is water transportation by Lake Calumet, and on the other the Illinois Central railroad tracks, while but a short distance away is the junction of the innumerable roads leading into Chicago. The structures will be of brick and stone, having 1,130 ft. of frontage and facing the double track of the Illinois Central railroad. They will consist, first, of two parallel buildings for erecting shops 690 ft. long and 87 ft. wide. The central section, containing the offices and store-rooms, will be 100½ ft. long and 100 ft. deep, three stories high, with a tower rising to a height of 146 ft. In the rear of these will be a series of four buildings, covering an aggregate frontage of 1,047 ft., with a general depth of 200 ft., forming the wood machine shops, blacksmith shops, variab-room, repair shops and two erecting shops. Still back of these will be another erecting shop, 474x86 ft., a dry kiln 150x80, and a foundry 130 ft. front and 200 ft. deep. These buildings are compactly located as regards each other, making them convenient of access. The erecting shops will have stalls for 50 passenger cars and 100 freight cars at one time. Tracks running between the various shops will be provided with numerous turn-tables, so that cars can be run in and out without switches.

The Edison telephone connects the British Parliament buildings directly with the London newspaper offices, so that the debates can be reported and put in type an hour earlier in the morning than heretofore. It was but lately that the London Times was printed on a Yankee press; now it is a Yankee that helps on the chiu music in Parliament, and we half suspect that they have a Yankee type printing machine connected with it, one that is claimed to set up 100 lines an hour, instead of 40 by hand labor. Really, Brother Jonathan can now help the old man considerably.

PIN MANUFACTURE.—A writer, who has been looking into the statistics of pin manufacture, makes the statement that while 50 years ago it took one man a minute to make 14 pins, to-day, with our improved automatic machinery, a single workman can make more than 1,000 in the same time.

AMERICAN WATCHES.—The American Watch Co., of Waltham, Mass., has lately received an order from the British government for 372 watches, intended for the use of conductors, engineers, station masters and other employees of the state railroads of India. This is the third large order received by the company from the same source, and, like the former ones, was obtained in public competition with foreign manufacturers. The London *Jeweler and Metal-worker*, in its issue of January 15th, observes, in reference to this order: The contract for watches to be used by the officials of the Indian state railways has again been secured by the American Watch Co. This is the third time Messrs. Robbins & Appleton have received this distinction, which is not a barren one, for it must be evident to the most prejudiced individual that the timekeepers supplied on the previous occasions must have given satisfaction, and answered the tests required of them. This is a mortifying fact for Englishmen, especially for those who believe that were manufacturers here to show more enterprise, they would be able to compete advantageously in the manufacture of all grades of watches.

STATISTICS OF THE IRON AND STEEL INDUSTRY. Mr. James M. Swank, Secretary of the American Iron and Steel Association, has nearly ready for distribution, to members of the association, a directory of the iron and steel industry of the U. S. This compilation will give the name and location of every blast furnace, rolling mill, steel works, forge and bloomery in the country, with full information concerning each, especially with relation to the character and capacity of the same. From this valuable source of information we glean the following leading statistics: Number of completed blast furnaces, March 1, 1880, 697; number in process of construction, 44; annual capacity of completed furnaces, 13,000,000 tons. Number of completed rolling mills and steel works, 352; number now in process of construction, 10; number of puddling furnaces, 4,467; number of heating furnaces, 2,419; number of trains of rolls, 1,397; annual capacity of rolling mills for finished iron, 400,000 tons; annual capacity of rail mills for heavy rails, 2,150,000 tons; number of nail machines, 4,152; number of Bessemer steel works, 11.

RAILROAD SCALES FOR SOUTH AMERICA.—The bark *Amy A. Lane*, was recently loaded with American goods at New York, for Rio de Janeiro. An important part of her cargo is a lot of 40 large railroad scales, built by the Howe Scale Company for the Dum Pedro railroad, of Brazil. This line is one of the most important in Brazil, running from Rio into the heart of the agricultural region, and enjoys the special patronage and care of the Emperor, in whose honor it is named. The selection of the Howe scales for use on this road is a compliment to American mechanics, which should be appreciated, and shows a preference for them in that country over all others.

AMERICAN VS. ENGLISH MECHANICS.—An English manufacturer traveling in America for the purpose of inspecting various industrial establishments, recently wrote: "I spent some hours recently at the Cleveland rolling mills. They have a wire mill attached for drawing nothing but Bessemer steel wire, of which they turn out 75 tons per day, and have one room with 1,000 small blocks, each man tending 32 blocks, whereas in England we consider a man that runs eight blocks of steel is a wonder. So much for your country. I saw it with my own eyes, and was never more astonished."

THE COTTON-SPINNING INDUSTRY OF THE WORLD.—This industry, of the entire world, consists of 71,250,000 spindles, of which more than half (or 39,500,000) are operated by British manufacturers. The U. S. has 10,050,000; France has 5,000,000; Germany, 4,800,000; Russia, 2,860,000; Switzerland, 1,870,000; Austria, 1,800,000; Spain, 1,775,000; Italy, 900,000; Belgium, 800,000; India, 1,275,000; Sweden and Norway, 310,000; Holland, 230,000; and other countries, 80,000 spindles.

THE INDIA RUBBER BUSINESS.—There are in the U. S. and Europe more than 150 manufacturing of India rubber goods. These employ from 10,000 to 15,000 operatives, and consume annually about 40,000,000 lbs. raw material. The bulk of the crude rubber, and the best quality, is brought from Brazil, though considerable quantities are obtained from Central America, Africa (especially Madagascar), India and the islands of Borneo and Sumatra.

BUILDING STONE FROM FURNACE SLAG.—Building stone is manufactured from furnace slag on a large scale at Osnabruck, Germany. One establishment delivered 6,000,000 brick during the last year. The artificial stone is valuable for ventilation, as it permits four times as much air to pass as ordinary building stone; it also requires 20 times as long to saturate the stone with moisture as it does the bricks baked from clay.

AMERICAN WINDMILLS IN ENGLAND.—Windmills of American manufacture continue to be exported in considerable numbers, particularly to the British colonies. One of the largest lately shipped had a diameter of 24 ft., and single casing in it weighed 5,000 lbs.

The largest Bessemer converters at work in England are the 10-ton converters at Sir John Brown & Co.'s works.

PACIFIC MACHINERY DEPOT. H. P. GREGORY & CO.,

Nos. 2 and 4 California Street, San Francisco.

Importers and Dealers in every description of

MACHINERY!

Sole Agents for the Pacific Coast for

BUCKEYE

Engine Company

J. A. Fry & Co.'s Wood-Working Machinery; Bement & Sons' Machinists' Tools; Blake Steam Pumps; Knowles Steam Pumps; N. Y. Belting and Packing Co.'s Rubber Goods; Sturtevant Blowers and Exhaust Fan; Tanite Co.'s Emery Wheels and Machinery; Payne's Vertical Engines and Boilers; Perry's Centrifugal Pump; Judson's Standard Governors; Dreyfus Self-Oilers; Gould Mfg. Co.'s Hand and Power Pumps; Eclipse Windmills; Disston & Sons Circular Saws; Otto Silent Gas Engine; Dues' Elevator Cups; Ballard's Oak Tanned Belting.
Also on hand and for sale A FULL LINE OF MILL AND MINING SUPPLIES.

HYDRAULIC GRAVEL ELEVATORS,

For working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

JOSHUA HENDY,

No. 51 Fremont Street, Office of the Hydraulic Gravel Elevating Mining Co., S. F.

RICKARD & DURDEN'S

Anti-Scale Compound,

FOR THE PREVENTION AND REMOVAL OF

INCRUSTATION IN STEAM BOILERS.

Ten years' trial in widely separated localities, having demonstrated the value of this invention, and its applicability to different qualities of waters, we now offer it to Engineers and Steam Boiler Owners, with the fullest confidence as to the result.

SOLD ONLY BY

BERRY & PLACE MACHINERY CO.

323 & 325 Market St., San Francisco.

Mining and Scientific Press Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1850—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice free. Address, DEWEY & CO.,
Office MINING AND SCIENTIFIC PRESS and PACIFIC RURAL PRESS, 202 Sansome Street, S. F.—1879.

MONEY TO LOAN!

\$500,000

To loan, in one sum or in amounts to suit on Wheat Lands, Wheat in Warehouses, and other good collaterals at current rates of interest.

Savings Bank Books.

California St., San Francisco.

We would call the special attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our stock of Clay Crucibles, Muffles, Dry Cups, etc., manufactured by the Patent Plumbago Crucible Co., of London, England, for which we have been made Sole Agents for the Pacific Coast. Circulars with prices will be sent upon application.
Also, to our large and well adapted stock of

Assayers' Materials & Chemical Apparatus,

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.

Our Old and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grams and grammes, will be sent free upon application.

JOHN TAYLOR & CO.

W. BRUCKNER'S**ROASTING FURNACE**

AND

Ore Pulverizers.

(Awarded the Premium Gold Medal at Naples, Italy.)

The furnace is especially adapted for roasting rebellious ores; there are more than fifty in use in Colorado, giving perfect satisfaction.

The Ore Pulverizer is built in different sizes. It is preferable to Stamp Mills because it requires less power and less repairs than Stamps. No extra expense for setting up, and no foundation. Less weight and less cost than stamps. Furnished also in sections for packing.

For circulars and prices apply to

Machinery.**GOLD AND SILVER****Grinding and Amalgamating MACHINERY.**

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

**SPERRY'S****Wrought-Iron Frame**

FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter, Shafting, Pulleys, etc. Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,550.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

MOREY & SPERRY,

No. 145 Broadway, - NEW YORK.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

NOW READY!

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW on SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Quarto. 234 Illustrations.

By ROBERT GRIMSHAW, Ph.D., M.E.,

Member of the Jury on Wood-working Machinery at Paris Exposition of 1878.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand, ash, iron, jig, drag, circular, cylinder and band saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, sawing, gumming, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 36 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copy, 100 pages. Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the price is this date made \$2.50, postage paid.

ROBERT GRIMSHAW,

624, 626 and 628 Market Street, Philadelphia

March 10 1880.

Recent Decisions Relating to Patents, etc.

We give below brief abstracts of decisions rendered upon patent cases in litigation, for the benefit of our readers:

DECISIONS OF THE U. S. COURTS. Roberts et al. vs. Schreiber.

U. S. Circuit Court, Western District of Pennsylvania. Decided June 10, 1880; Strong, J.

1. Reissued Letters Patents No. 6,253, granted to E. A. L. Roberts, January 6, 1875, the claim in which is for "the method or process of increasing or restoring the productiveness in oil-wells, by causing an explosion of gunpowder or its equivalent at or near the oil-bearing point, in connection with superincumbent fluid tamping, substantially as described," declared to be for the same invention as his original patent dated May 20, 1866, and sustained.

2. The decision in the case of Roberts vs. Dickey & Fisher, 632, construing the true meaning and scope of such original patent, approved.

3. The application of a blast in a bore-hole sunk in an ordinary well is not an anticipation of a process by which a torpedo may be exploded many hundred feet below the surface of the ground and below the top of the rock through which an artesian well has been sunk, and at the exact point in the well where the effect of such explosion is desired, with a water tamping sufficient to confine the effect to the vicinity of its location.

4. Unsuccessful and abandoned experiments cannot avail to invalidate a patent to an inventor who has disclosed to the public an invention the utility of which has been demonstrated by its general adoption.

5. The cause that works successful results cannot be the same as that exhibited in abandoned experiments, and holding the latter up as anticipation of the former, is but an illustration of what is very common—an attempt to defeat a meritorious invention by proof that something similar had been previously known, though it had never been perfected and had never been any useful combination to human knowledge or convenience.

6. The process invented by Roberts, as disclosed by his specification, does not require that the superincumbent fluid tamping should fill the well, but that there should be a sufficient column of fluid to confine the effect of the blast.

7. Letters Patent No. 47,453 granted to E. A. L. Roberts, April 25, 1865, for improvements in apparatus for exploding gun powder or the explosive material in artesian or other similar wells, construed and sustained.

* More complete reports of the proceedings may be found on file in the office of the MINING AND SCIENTIFIC PRESS Patent Agency, 202 Sansome street, S. F.

"THE CALIFORNIAN" FOR SEPTEMBER.—This sprightly home monthly, which is welcomed by an increasing list of appreciative readers, offers a dainty table of contents for September. We have had only time for a casual reading, but the flavor of several articles was distinctly pleasant. The spirit of Mr. Clement's opening article on the political maxim, "To the Victors Belong the Spoils," leads in the right direction and will command attention. Mr. Sam. Williams follows with a readable account of the Algerian patriot, Abd-el-Kader. There is a good sketch of John A. Sutter, by Alexander Del Mar; and the vineyards and wines of Napa valley glow and sparkle under the deft hand of Sallie R. Heath. A very interesting paper is Hon. Henry A. Pierce's account of the early discoveries of the Sandwich Islands. New England people especially will be delighted with Prof. Martin Kellogg's charming sketch of a "New England Farm." A serial, entitled "A Strange Confession," promises to be an interesting story. D. S. Richardson, for several years attached to our legation in Mexico, relates his experience in a very agreeable way. In addition to these principal articles, there are many minor ones and some bits of excellent poetry, the whole combining to form perhaps the best number of the magazine yet published. The Californian is the peer of the first magazines in the country, and to maintain its excellence the publishers have discovered that they must raise its price up to the Eastern rate for similar monthlies. Accordingly, they announce that after October 1, 1880, the yearly subscription will be advanced to \$4, and single copies to 35 cents. It is published at 202 Sansome street.

SHOCKING THE PHYLLOXERA.—We hear in a very round-about way that a French chemist thinks he is warranted in asserting that the phylloxera can be destroyed by electricity. He sends a current by means of the Ruhmkorff coil directly to the roots of the vines, killing, as he says, not only the insect, but its eggs. When the steam is turned on the Ruhmkorff the insects are at once seized with a desire to shuffle off their mortal coil—so to speak.

At Odessa, three weeks ago, were married two mites of creatures, the man being 30 years old and weighing 19 pounds, and the woman 22 and 13 pounds in weight.

Address of Hon. A. A. Sargent.

CONTINUED FROM PAGE 118.

in theory and practice, its highest stations to the attainment of the humbleness; a land where free men, free thought and free labor gave witness to the beneficence of the maxim that all men are created equal; that distinctions of birth are pernicious, and only distinctions of merit are worthy of recognition; gave its crowning stamp to industry, and acknowledged it as the condition of progress and prosperity. It was a grand spectacle when America greeted the nations assembled on its soil and distributed eagerly-sought honors to artistic and mechanic excellences.

Former Oppressions and Contempt for Labor.

This recognition of the dignity and value of labor is entirely modern. Not many ages ago the artisan was a serf, or, if nominally free, the prey of great and petty tyrants. It is a long etride in England from the condition of Gurth, born thrall of Cedric the Saxon, to the modern barbor ennobled by the king for his inventions. There is as great a step between the expulsion of the Huguenot artisans from France and the giving, by republic and empire alike, of medallions and ribbons to such workers, and glorifying them as the strength of nations. The extent and importance of the successive immigrations to England, caused by the blind cruelty of the ruling powers of the continent, are well set out in Lecky's recent admirable history of England in the eighteenth century. When the news of the intended entry of the Duke of Alva into the Netherlands was known, more than 100,000 persons in a few days abandoned their country. Great numbers of them took refuge in England, and they were followed in 1572 by a crowd of French Huguenots, who had escaped from St. Bartholemew, and in 1585, on the occasion of the sacking of Antwerp, by about the third part of the merchants and workmen of that city. A century later the revocation of the edict of Nantes produced a new immigration of French protestants variously estimated at from 50,000 to 100,000. Several thousand Germans, chiefly from the Palatinate, went over in 1709; many others in 1732, after the persecutions in Salzburg; and toward the middle of the century a renewal of persecution in France was followed by a fresh French immigration. In this manner the commercial classes in England were at length thoroughly pervaded by a foreign element. Spitalfields was almost wholly inhabited by French silk manufacturers. A colony of French protestants settled in Edinburgh, where they introduced the manufacture of cambric. Forms of industry before entirely unknown in England were introduced there. Cloth makers from Antwerp and Bruges, lace makers from Valenciennes, cambric makers from Cambrai, glass makers from Paris, stuff weavers from Meaux, potters from Delft, shipwrights from Havre and Dieppe, silk manufacturers from Lyons and Tours, paper makers from Bordeaux and Auvergne, woolen manufacturers from Sedan and tanners from Touraine, were all plying their industries in England. The manufacturers of silk, damask, velvet, cambric and baize, of the finer kinds of cloth and paper, of pendulum clocks, mathematical instruments, felt hats, toys, crystal and plate glass, all owe their origin in England wholly or chiefly to Protestant refugees, who also laid the foundation of scientific gardening, introduced numerous flowers and vegetables that had before been unknown, and improved almost every industry that was indigenous to the soil. What England thus so largely gained was lost by France and the Netherlands. In the former country the arts were nearly stamped out, and the primal causes of the revolution were set in motion. It is true that these artisans were not expelled from France because they were such, but notwithstanding that fact, they were coldly received in England, and occasionally mobbed, from the insular prejudice of the population. The age was not wise enough to appreciate the value of the worker.

The Craftsman in Literature.

What were called the free cities in Europe, which were nuclei of arts and trade, maintained their scanty privileges, bought with money of necessitous nobles, only by constant repurchase or by dint of arms. The tradesman was looked down upon as a grovelling being, the alternate sport and prey of the powerful. Shakespeare reflects the sentiment of his age when he makes a fool of Bottom the Weaver, a brutal ruffian of Jack Cade and fills Casca's mouth with bitter sarcasm on the common people. The plays of the restoration are full of unsavory jests at the expense of craftsmen. Even Hume designated the whole class of workers as "the industrious vulgar." When enlightened minds thus branded labor as ignoble its esteem in general society was indeed low. Early English Parliaments assumed to fix its wages at a miserable pittance, and to regulate the prices of its products. The transition from such a state of things to the entire emancipation of industry, the enactment of patent laws in reward of invention and the conferring of social distinctions upon eminent inventors, is so great that it needs a glance backward to appreciate the distance traversed.

The Toiler in the U. S.

In this land the laborer and artisan have least reason to be discontented with their lot. While the fluctuations of business may affect them, as they do all other classes, the laws and customs of society are such as to give to them every pro-

tection, facility and deserved honor and reward. He is certainly not a friend to the toiler who seeks to overthrow the institutions here enjoyed, or destroy the conditions which secure to the possessor sither inherited or earned wealth. I know such projects are not the product of American soil, and are not in harmony with our traditions. They interfere with the rights of laborers, they threaten the public peace, and tend to inaugurate a reign of mob violence and misrule. Unless checked, such ideas may lead to serious misfortunes, and to none greater than to the class whose name is profaned as the agent and proposed beneficiary.

The Doctrine of Agrarianism.

The doctrine that property is robbery is false, and its practical enforcement would paralyze enterprise and destroy every vestige of national and individual prosperity. It would alike deprive the artisan of the product of his labor and the capitalist of the proceeds of his investment. Barbarism would be invited to reign where civilization now rules. Wealth and honors are an ever-alluring reward held out to successful workers. Deprived of such incentives, society would become stagnant. Agrarianism may find an account in substituting for the daily earnings of the world a distribution of past accumulations; but these would soon be devoured, and the impoverished multitude resume its labor or perish. Meantime the hand on the dial of progress would have been put back a dozen generations. That state of society is best which respects equally the interests of those who have and of those who would acquire, which holds in just equilibrium the rights of capital and labor.

Cheap Labor Means Squalid Living.

I am far from believing that the beet has yet been said and done to reconcile the interests of these two great elements. It is possible that the future may develop a co-operative system by which the wages of the laborer shall be an assured part of the profits of capital, in those enterprises of capital where profit is the object. As at present developed, the objection seems to be that labor cannot wait for good seasons, while capital can, and may starve in those times of depression when no profits are made. However this may be, and however the enlightenment and humanity of the future may solve the great problems of social and industrial life, one thing is clear to my mind—that is, that it is not to the interest of society to cheapen labor. Cheap labor means squalid living, limited education, degradation and want. The laborer is worthy of such hire as shall enable him to maintain the self-respect and decency of an American citizen. Any circumstance depriving him of this, whether the presence of slavery, the influx of Mongolians, or foreign competition in home markets, should awaken the solicitude of statesmen and lead to remedial measures commensurate with the evil.

Mechanics' Fairs and the Progress of the State.

And now, in conclusion, I congratulate you upon the successful inauguration of the Fifteenth Industrial Exhibition of the Mechanics' Institute of San Francisco. It marks and promotes the progress of the State. It performs in its sphere the work done by great International exhibitions in theirs. It tends to stimulate enterprise, industry and invention, by exciting wholesome emulation among its many exhibitors. There are great possibilities of good in your enterprise, in lasting benefit to all the interests of the coast. A glance at the multifarious articles exhibited, impresses the idea that many of them are better than those which the world generally has in use. Hence our productions are making their way abroad. American reaping machines were recently engaged in a competitive trial at Bucharest, and so delighted the Roumanian farmers that large orders followed. It was once contemptuously asked, "Who reads an American book?" Irving, and Motley, and Prescott, and Longfellow and Whittier, and many others answered the question. It has more recently been asked, "Who drinks an American wine?" California answers by shipping cargoes of wine to Europe. There is a broad field for American products and American enterprise, ready for industry and tact to enter. As these exhibitions encourage excellence of production, they fit our products to compete advantageously with others in the markets of the world, and lead up to the day when California will realize the advantages of its geographical position, in the possession of a commerce that will embrace Asia and the isles of the Pacific seas.

TORN BY HYENAS.—The telegraph brings the news of a terrible occurrence at Winchester, Va., on Tuesday the 17th. inst. It appears that while Coup's circus and menagerie troupe was parading the streets the keeper of a cage of hyenas was seized and torn almost in pieces by the ferocious animals. The keeper, whose name was Drayton, made a most heroic effort to save his life, and, in the face of the tremendous peril of his position, assumed his usual cool tone of command, but the infuriated beasts did not heed him. The people who witnessed the man's brave struggles for his life were powerless to help him, as they did not dare to open the cage. After desperate efforts some of the showmen succeeded in rescuing the hapless keeper, but he was so frightfully wounded as to leave small hope of recovery.

The population of Oregon will foot up about 170,000. It was 90,000 ten years ago. The increase is about 90%. This is a remarkable gain.

Leaf-Variation in Acacia Trees.

[CONTINUED FROM PAGE 121.]

to produce foliage enough to hide them.

But in our hard battle we lost forever our original leaves, and we are only permitted to bear them in infancy. In the second year we have to cast them away, and it seems almost like a dream that we ever had them, so that we scarcely realize it. Our many relations (some 220) have already forgotten that they once lived in the loveliest country on earth, and they do not know what those few leaves they bring forth in childhood mean; and you, wise men, if it were not for us, you would be as ignorant as they are. The land that saw our struggles and hardships, where we found refuge, is becoming the home of another race. Assisted by man they gain a foothold, until their deadly shade deprives us of the life-giving sun. We must have bright, strong sunlight. In bright California we have still found another home. In the rocky hills and barren sand we prepare the place for others, until in due time here also we shall be driven out.

From Lake County.

EDITORS PRESS:—Lake county as a sanitarium, on a large scale is destined to prove a great success. Nowhere can you find more picturesque scenery, brighter skies or purer air, while medicinal springs of every degree of temperature, and every conceivable mineral compound, are pouring their healing waters, inviting the sick and decrepit of all classes to come and be cured of their maladies. The immense number and variety of the springs and the great merit of many of them is truly wonderful. We spent a few very pleasant days at Seigler springs, a few miles from Lower Lake, which are once more opened for the accommodation of visitors, under the management of W. T. Garratt, Esq. Few springs stood higher in popular favor than these till they were closed from the public. Many old visitors will be glad to know that the public are once more invited to come and partake of their healing waters; and under the popular management of Mr. Garratt and his accomplished lady the place should become once more a favorite resort for all deserving classes. Some of the hot and steaming springs here are but little less wonderful than the most noted geysers.

About a mile and a half from Seigler springs it was our good fortune to meet our old and esteemed friend, H. W. Rice, in his pleasant home, nestled amid surrounding hills and natural groves, at the foot of Mt. Hannah, from which it is separated by a beautiful sheet of water. Twenty-eight years ago, at the close of a five months' voyage around Cape Horn, we parted from him in San Francisco, each eager in the pursuit of fortune—determined to make his mark, if possible, in the State of his adoption, each in his own way. I find our friend Rice has done or is in a fair way to do both. And right nobly has he earned the prosperity that awaits him. You doubtless remember him as the inventor of the "straw-burning engine," which he has brought into extensive use by his persevering energy.

His saw and planing mill here is very complete, showing everywhere the evidences of his inventive genius, and is capable of turning out a large amount of lumber of almost every variety for house building, mining, fencing, etc. He showed us fine oak lumber for organs that he was getting out for an organ builder at Kelseyville. We were shown specimens of oak door-panels got out at this mill that were perfect gems. Though the mill has been in operation 15 years, he has made but little impression upon the groves of timber surrounding him. But in his ceaseless war upon these giants of the forest, friend Rice has not forgotten the amenities of life or the gentler, kinder duties due to home and the home circle, so often neglected or utterly ignored by our California fathers and husbands in their eager pursuit of gold. I hardly know which to admire most—the energy and indomitable will that has thus compelled fortune to smile upon his labors, or the marked and constant effort of himself and noble wife to make home beautiful and attractive to their children, as well as to themselves—not, as is too often the case, a mere place to eat and sleep, but a real home, a rest for the heart as well as the body—a place of loving words and smiles, a joyous remembrance forever. Would that we had more such. Loving, Christian homes in which to educate our children would do more for the real prosperity of California than years of legislation. Mr. Rice has fitted up one room in his dwelling for a pleasant school-room, where his children are daily instructed by a competent teacher, and ever Sunday evening Mrs. Rice receives the children of their employees in their sitting-room for instruction in Sunday-school lessons. The two happy evenings my friend and I spent in that cheerful sitting-room, with its bright, blazing wood fire, surrounded by that pleasant family circle, will not soon be forgotten.

Soda Bay, July 14, 1880. S.

MEMPHIS, Tenn., has lost 8,000 in population in ten years, and is the only city in the Union that has decreased, although some cities have remained almost stationary.

News in Brief.

Fifty ladies are struggling for medical honors in Paris.

The Santa Clara Agricultural fair begins October 4th.

There are nine tenant-farmers in the British Parliament.

The census shows not a woman in Greenland, Vt., over 30.

Adelaide Neilson, the actress, died suddenly in Paris, Aug. 15th.

The demand at the Treasury for standard silver dollars is steadily increasing.

John Lume, of Astoria, killed a 900-pound elk recently on Saddle mountain.

Sir Stratford Canning, for many years British Ambassador to Turkey, is dead.

The cultivation of casava and arrowroot is being generally embarked in by Honda farmers.

Major-General Grimes of the Confederate army has been assassinated in North Carolina.

The New Orleans schools have been closed until there shall be money enough on hand to pay expenses.

Lockjaw runs in a family in Camden, N. J., three members of which have recently died from that cause.

In Illinois a duel was recently fought with coffee and blank cartridges, and they shook hands and parted.

The Tokio (Japan) Times says that a shock of earthquake is probably felt in some part of the island every day.

Heavy fires are raging in the timber in various portions of Oregon. No serious damage is reported as yet.

At the signal station at the top of Mt. Washington, the other day, the mercury marked 31 degrees and water froze.

Some ladies at Saratoga wear red jackets of breakfast, and look like members of the old volunteer fire department.

The New Haven police recently broke up a street fight by throwing water on the combatants with a fire engine.

Tuesday, Aug. 9th, 2,000 acres of pasture on Dry creek, Alameda county, were burned over. Cause, careless hunters.

The far trade on the northeast coast has been very good this year, the catch of fur-seal and bear being unusually large.

Work on the Normal School building at San Jose is progressing rapidly. The force of men has been increased to eighty.

Warehouses are crowded with wheat at Merced. Unless the farmers begin to sell, there will not be storage room.

Rochester is to have a colossal tower surmounted by an enormous statue of Mercury. It will advertise a tobacco factory.

Plates and jewelry to the value of £20,000 have been stolen from the residence of Lord Eldon, near Warthorn, England.

Threats are made that the Land League will prevent the collection of rents in Ireland against all the power of England.

H. E. Barton of Lake valley, El Dorado county, has lost 800 acres of pasture and two miles of fence from fires this year.

A colored preacher in Georgia makes his parishioners work out his salary on his farm when they have not money to pay it.

There is a funny report that it is fashionable in Paris just now for brunettes and medium blondes to dye their hair a blue black.

A boy was given three months of hard labor in the workhouse in Cambridge, England, for plucking a rose and a sprig of geranium.

Senator Bruce, of Mississippi, is reported to be the possessor of two large plantations in his State, and has a fortune also of \$200,000.

Two boys in Paris settled a dispute by having a duel with knives, which they threw at each other. One was killed, and the other arrested.

The President of the Imperial Bank of Germany has, in a remarkable treatise, exposed the mistake made in abolishing the silver standard.

A serious riot took place in Glasgow on Saturday, Aug. 14, between Home Rulers and Orangemen. Two policemen were fatally injured.

White satin sun-shades elaborately painted by hand are carried by some of the fashionable women who ride in open carriages along Bellevue avenue at Newport.

A man, who was one of the five in a wagon which was struck by a locomotive in Syracuse, says that the engineer was flirting with a young lady at the time.

Erskine Wood, shot by Hiram C. Briggs at Coeymans the other day, ran half a mile and lived fifty-eight hours after the bullet had passed through his heart.

The man who fired at Lord Lytton, Viceroy of India, in December, and then declared himself to be insane, has recovered and has been committed for trial.

An English rector has omitted the prayers for Parliament since the Liberals came into power, and says that "he does not think such a lot worth praying for."

Lindsay Munn has been messenger at the office of the Secretary of the Navy for more than half a century, having been appointed under John Quincy Adams, July 15th, 1828.

They are showing inventions in England in devising pretty additions to weddings. Four little children dressed as sailors holding the bride's train in the bridal procession was one of the features of an English wedding last month.

There is a man in England who is a willing defendant in a suit for divorce by his wife, co-respondent in another man's suit for divorce, and engaged to marry a lady who is at present the wife of a nobleman.

GOLD AND SILVER MINES IN NEW YORK.

Prospecting for occurrences of gold and silver in the State of New York would appear to have reached the stage of fever heat. Over 100 claims of gold and silver discoveries have been filed in the office of the Secretary of State within the past year, and since the first of last June three or four claims have been filed in a day. Nearly all of the alleged discoveries have been made in the region that is embraced in Hamilton, Saratoga and Fulton counties, which form the southern edge of the great Adirondack wilderness. Almost all the discoveries are said to be gold and silver, while a few specify gold or silver alone. According to the New York Sun, the following are said to be the ascertained facts: That gold and silver really exist; that no one really knows whether they exist in paying quantities or not; that two mines are being worked; that attempts have been made to sell one claim; that almost everybody in that region has got the gold fever; that there is more or less expert prospecting going on; that there is a possibility that there is a very rich mining country in the region described; that the probability is it will cost more than it will come to to mine gold and silver in northern New York.

MINING WORKS DESTROYED.—The works of the Copper Mining Co., at Sponceville, Nevada county, of which we gave a brief account last week, were destroyed in a singular way on the 11th inst. The Nevada Transcript gives this statement of the occurrence: The vein of copper ore in the mine is very wide, and the owners have been hearing it out its whole width and to a great height, with only here and there a long timber to support the roof. On Wednesday the immense weight of ground, and the hoisting works which were built over the mine, caused the supports to give way, and the building and machinery, together with two men, the engineer, named Hughes, and another man, sank down a distance of 25 ft. Directly afterwards the hoisting works took fire, and in five minutes they were a mass of flames. The men fortunately escaped through the air shaft. Mr. Hughes sustained a dislocation of the shoulder. It was a fortunate escape from a horrible death.

Pocket Mining Atlas,

Containing the principal mining districts in the United States. Compiled from the latest official surveys and the most authentic sources by Edwin Bolitho. Sent, post-paid, on receipt of \$1. Address, Dewey & Co., 202 Sansome St., S. F.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omissions of agents.

Quinine and Arsenic

Form the basis of many of the Ague Remedies in the market, and are the fast resort of physicians and people who know no better medicine to employ for this distressing complaint. The effects of either of these drugs are destructive to the system, producing headache, intestinal disorders, vertigo, dizziness, ringing in the ears, and depression of the constitutional health. Ayer's Ague Cure is a vegetable discovery, containing neither quinine, arsenic, nor any deleterious ingredient, and is an infallible and rapid cure for every form of Fever and Ague. Its effects are permanent and certain, and no injury can result from its use. Besides being a positive cure for Fever and ague in all its forms, it is also a superior remedy for Liver Complaints. It is an excellent tonic and preventive, as well as cure, of all complaints peculiar to malarious, marshy and miasmatic districts. By direct action on the liver and biliary apparatus, it stimulates the system to a vigorous, healthy condition.

FOR SALE BY ALL DEALERS

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus, terms of subscription, etc., and request that they circulate the copy sent.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for \$3 per (half-yearly) volume. In cloth and leather binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

INVENTORS, and others interested, will receive DEWEY & CO.'S MINING AND SCIENTIFIC PRESS Patent Agency Circular free on application at this office. It contains 42 pages of hints and information about Patents, Patent Laws, Patent Office Regulations, and how to obtain valid patents.

HOW TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So he sure and send us notice by letter.

J. G. COLMERT is requested to report to this office from Humboldt Co.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

DIVIDEND NOTICE.

OFFICE OF THE

Consolidated Virginia Mining Company,

Nevada Block, Room 26, S. F., August 7, 1880.

At a meeting of the Board of Directors of the Consolidated Virginia Mining Co., held this day, a Dividend (No. 53) of Fifty (50) Cents per share, was declared, payable on Monday, August 16, 1880. Transfer books closed until the 17th inst.

A. W. HAVENS, Sec'y.

DIVIDEND NOTICE.

OFFICE OF THE

Eureka Consolidated Mining Company,

Nevada Block, Room 37, S. F., August 16, 1880.

At a meeting of the Board of Directors of the above-named Company, held this day, a dividend No. (58), of Fifty cents per share was declared, payable on FRIDAY, the 20th day of August, 1880. Transfer books closed until the 21st instant.

W. W. TRAYLOR, Secretary.

Gover Mining and Milling Company.

Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.

Notice is hereby given that at a meeting of the Directors held on the Eleventh day of August, 1880, an assessment (No. 43) of 20 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 402 Front street, room 8, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Thirtieth day of September, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Monday, the Eleventh day of October, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

Office—402 Front street, room 8, San Francisco, California.

INCERSOLL
ECLIPSE ROCK DRILLS.

The Most Economical Air Compressor in the Market.

MINERS' HORSE-POWER.

One Horse can easily haul over 1,000 pounds at a depth of 500 feet. The Power is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is hauled to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

and Public Buildings.

Steam Engines and all Kinds of Mill and Mining Machinery.

Fulton Iron Works.

Hinckley, Spiers & Hayes.

(ESTABLISHED IN 1855.)

Works, Fremont and Howard Sts. | San Francisco, Cal. | Office, No. 213 Fremont St.

MANUFACTURERS OF

Marine Engines and Boilers,

Propeller Engines either High Pressure or Com-
pound Stern or Side Wheel Engines.

Mining Machinery.

Hoisting Engines and Works, Cages, Ore Buckets, Ore
Cars, Pumping Engines and Pumps, Water Buckets,
Pump Columns, Air Compressors, Air Receivers,
Air Pipes.

Mill Machinery.

Batteries for Dry or Wet Crushing, Amalgamating

Engines and Boilers

of all kinds, either for use on Steamboats and made in accordance with the
Act of Congress regulating the same, or for use on land. Water Pipe, Pump
Air Column, Fish Tanks for Salmon Canneries of every description.
Boiler repairs promptly attended to and at very moderate rates.

Pans, Settlers, Furnaces, Retorts, Concentrators, Ore
Feeders, Rock Breakers, Furnaces for Reducing Ore
Water Jackets, Etc.

Sugar Machinery.

Crushing Rolls, Clarifiers, Vacuum Pans, Air Pumps,
Concentrators, Bag Filters, Charcoal Filters, Blow-up
Tanks, Coolers and Receiving Tanks.

Miscellaneous Machinery.

Flour Mill Machinery, Saw Mill Engines and Boilers,
Dredging Machinery, Oil Well Retorts, Powder Mill Ma-
chinery, Water Wheels.

PACIFIC IRON WORKS,

First and Fremont Streets, between Mission and Howard, San Francisco, Cal.,

RANKIN, BRAYTON & CO.,

Manufacturers of

ENGINES, BOILERS, MARINE AND STATIONARY. PUMPING, HOISTING, AND MINING MACHINERY
INCLUDING BATTERIES, AMALGAMATING PANS AND SETTLERS, CONCENTRATORS, ORE FEEDERS,
CRUSHING ROLLS AND ROCK BREAKERS. ALSO, WATER JACKET SMELTING FURNACES,
FOR REDUCING LEAD, SILVER AND COPPER ORES, QUICKSILVER FURNACES,
RETORTS AND CONDENSERS, ROASTING AND CHLORIDIZING FURNACES,
SUGAR MILL MACHINERY, WATER WHEELS, Etc., ALL OF THE
LATEST AND MOST IMPROVED CONSTRUCTION.

Agents for the Allen Engine Governor, Bailey Air Compressor, Howell's
Improved White Furnaces, Walker's Compound Steam Pumps, Etc.

Pacific Rolling Mill Co.,

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with
Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when ad-
visable.

STEAM LAUNCHES, Barges and Steam Tugs con-
structed with reference to the trade in which they are
to be employed. Speed, tonnage and draft of water
guaranteed.

STEAM BOILERS. Particular attention given to
the quality of the material and workmanship, and none
but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING
MACHINERY made after the most approved plans.
Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size
made in suitable lengths for connecting together,
sheets rolled, punched, and packed for shipment ready
to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and
Water Pipe made by this establishment, riveted by
Hydraulic Riveting Machinery, that quality of work
being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam
Winches, Air and Circulating Pumps, made after the
most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City
Water Works purposes, built with the celebrated Davy
Valve Motion, superior to any other Pump.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER.

Several first premiums received
for Quartz Mill Screens, and Per-
forated Sheet Metals of every
description. I would call special
attention to my SLOT CUT and
SLOT PUNCHED SCREENS,
which are attracting much at-
tention and giving universal
satisfaction. This is the only
establishment on the coast de-
voted exclusively to the manu-
facture of Screens. Mill owners us-
ing Battery Screens exten-
sively can contract for large supplies at favorable rates.
Orders solicited and promptly attended to.

New Book on the Comstock.

The attention of MINING ENGINEERS and EXPERTS
is called to the new work by JOHN A. CHURCH, E. M. Ph.
D., on "The Comstock Lode, Its Formation and History." This
very exhaustive treatise on this famous lode is fully
illustrated with diagrams and colored charts showing
sections, ore bodies, etc., and will be of great interest and per-
manent value for reference. DEWEY & Co., Publishers of
the MINING AND SCIENTIFIC PRESS, are sole agents for the
sale of the work. Mr. E. M. SLEATOR will act as their
agent, and call on Mining Engineers and those interested in
the great lode in this city with a copy of the book for their
inspection.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot, PARKE & LACY, 21 and 23 Fremont Street. S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

FRUE'S ORE CONCENTRATOR OR VANNER.
Plunger Jigs, Revolving Screens,
CRUSHING ROLLERS, SAMPLE GRINDERS.

No. 145 Fulton St., CHICAGO, ILL.

Howell's Improved White Roasting Cylinders,
REVOLVING CYLINDERS AND ORE DRYERS,
Hoisting and Pumping Machinery.

STEIGER & KERR'S CONTINUOUS DISCHARGE AND GRINDING PAN.

This pan is designed to receive ore direct from a rock breaker, and reduce it to the fineness necessary for amalgamation, thus taking the place of the ordinary stamp battery. The cost of this Mill places it within the reach of all; and one point of advantage not to be overlooked is the fact that the cost of erection, which adds so much to the expense of the stamp mill, after it leaves the foundry is, in this case, reduced to a fraction, as the Mill is complete in itself, and requires no expensive foundations, bed logs, battery frames, etc., but can be placed in position in a few hours after it arrives on the ground, without the aid of skilled labor. This simple arrangement, durable as it is simple, is a most important improvement in the working of gold ores, as it enables parties to construct and erect a mill at half the cost of a stamp mill, and with a great saving of time, and size of mill building. Each pan is capable of reducing 10 tons of average ore in 24 hours, the ore being first broken in a rock breaker, small enough to go through a half-inch screen. There is an important point in the action of this Mill, to which we desire to call the attention of miners and millmen. We allude to the grinding and scouring action on the gold before it is discharged. The value of this point cannot be overestimated, and it is not necessary to do more than mention the fact, as it will be at once recognized by all competent millmen who examine the pan in operation, and especially by those who have had to deal with tarnished or rusty gold, as it is commonly called, and which is often encountered in our mines, and which is such a cause of loss. The pan of feeding is the same as in the stamp mill, either an ore feeder or hand feeding being adopted, as may be desired. Parties interested in mining and mills can see the Pan in operation by calling at the OCCIDENTAL FOUNDRY, STEIGER & KERR, 137 First St., S. F.

LEFFEL'S IMPROVED WATER WHEEL.

PRICES REDUCED!

PATENTS REISSUED 1868.

The "OLD RELIABLE" with improvements, making it

THE MOST PERFECT TURBINE NOW IN USE

Comprising the Largest and the Smallest Wheels, under both the Highest and Lowest head used in this country. Our new Illustrated Book sent free to those owning water power.

Those improving water power should not fail to write us for New Prices, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

JAMES LEFFEL & CO., Springfield, Ohio,
and 110 Liberty St., N. Y. City.

FROM 14 TO 10,000 lbs. WEIGHT.

True to pattern, sound and solid, of unequalled strength, toughness and durability.

An invaluable substitute for forgings or cast-iron requiring three-fold strength.

Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc.

15,000 Crank Shafts and 10,000 Gear Wheels of this Steel now running prove its superiority over all other Steel Castings.

DEWEY & CO.'S Scientific Press Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

MINING AND SCIENTIFIC PRESS

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO.,
Publishers.

SAN FRANCISCO, SATURDAY, AUGUST 28, 1880.

VOLUME XLI
Number 9.

San Simeon Mining District.

This mining district is situated in San Luis Obispo county in this State, and has within its borders quite a number of promising quicksilver mines, and several coal mines, some of which will, when the promoters are able to work them properly, add considerably to the production of the State. It seems somewhat strange that the dormant wealth in this and other similar places should not have been more fully developed. There are many places where thousands of dollars would be realized from the ground in a short time, if sufficient capital were forthcoming to open the claims.

In conversation this week with Mr. David Lippman, of San Simeon, we learn that there are many quicksilver claims lying idle there, which will pay very well when quicksilver goes up again. The present low price of the metal prevents developments, and consequently many poor men have to sell out, while if they could keep their mines, they would realize from their work.

His instance to us the Polar Star mine, in San Simeon district. It has been worked to some extent, but not systematically. Some 500 tons of ore have been mined and 53 flasks of quicksilver produced, with very inferior appliances. A tunnel has been run 120 ft., and the ore body varies from 5 to 10 ft. wide, of 5% to 10% ore. There are two shafts on the mine. They have material enough in the mine to build a good furnace of 10 tons capacity, with plenty of wood and water for roasting and condensing. Mr. B. F. Chase has averaged a number of assays which shows the ore to have some 10% of mercury. This mine is idle at present, as are several more of similar character in the district. No doubt when quicksilver goes up again these mines will come to the front, but for the present their owners realize nothing from them.

San Simeon is on Geo. Hearst's ranch, and is the landing on San Simeon bay. The landing, warehouses, wharf, etc., belong to Mr. Hearst, his business there being under the intelligent management of Mr. E. C. Apperson. The place is so situated as to be the center of a fine dairy district, and the town is in a thriving condition. There is a whaling station at the point.

RICH QUARTZ STRUCK.—The recent strike of very rich gold-bearing quartz in the Rocky Bar mine, at Grass Valley, Nevada county, promises to be of great importance. The *Union* says that four candle boxes of rich specimens of the quartz were brought from the mine and exhibited in town, and that more of similar rock had been boxed in the mine. The extent of this rich nest is not known. The Ford & McDonald ground is on the same ledge as the Rocky Bar, and as the former produces rich rock all the time, it is probable that the considerable space of ground which lies between the workings of the companies will yield rock equally good. Another development has also been made in the Rocky Bar which is of the most encouraging character, and that is in finding a strong two-ft. vein at a few ft. from the bottom of the shaft, in the east drift. The ledge is heavy with sulphate, and is milling at the rate of \$30 per load. This is the heaviest vein yet found in the mine, and the most encouraging on account of its mineral characteristics. The ledge is entirely different in size and quality from that found above, and from its pitch promises to open out finely when the main incline is sunk deeper upon it. These promising finds in the mine are some 500 ft. apart, and, so far as is known, upon two distinct ledges, and they hold out the best encouragement the company has had since the mine has been opened. The Rocky Bar adjoins the New York Hill, which is now established as a reliable mine by the payment of frequent dividends.

In the last number of the *British Quarterly Review* the opening paper on "The Nations and the Commonwealth," speaks encouragingly of the growth among the rich of a spirit which robs class antagonism of its worst features, and what, it is predicted, will, before long, prove a solvent, under which the present trade organizations will become associative and cease to be combative.

The American Lubricator.

The lubricating of machinery by means of automatic devices, is of comparatively recent date. The old-fashioned oil cup, crude in its workings and wasteful in its distribution, was of doubtful expediency. The oil or tallow admitted directly to the cylinder or steam chest in large quantities, could not vaporize into steam, before it was thrown out of the exhaust pipe in a body, leaving behind little or no lubrication or benefit. Being applied but once an hour or even less frequently, the benefits were doubtful at the best, and when tallow, which was the favorite for cylinder lubrication, was used, the effects were often positively injurious, and it was no infrequent thing to find between the packing rings large balls of solid matter hammering against the springs, and eating the life and substances out of all the surrounding metal.

About four years ago the American Lubricator Co. commenced the manufacture of a device by which, through the counterpoise of condensed steam, oil could be admitted in the steam pipe at a point above the throttle, and in such limited quantities that each drop in its passage to the steam chest perfectly vaporized. Here then was a something which would penetrate as a vapor to every portion of the engine; the governor, the valves, the rings, the springs and the inner surface of the cylinder, and yet never in quantities which were not instantaneously ejected, before a cumulative effect could cause them to assume an injurious form. The supply, too, could be perfectly regulated from one drop a minute to one a second, and yet no admission of oil could take place until the opening of the throttle established a circulation. The oil being always held in a vessel which was in direct communication with the steam, was always ready for instantaneous vaporization. This would seem to be the acme of perfection in the saving of oil, and the highest possible point of utility in the lubrication of an engine.

Among the claims made for it not before enumerated are, that it imparts a regular motion to engines, because it lubricates the governor valve. It makes the throttle turn easy, keeps it from rusting, and saves packing and the grinding of it. It will pay for itself in fuel every two months, in oil in seven to ten months, and in wear of packing and labor every four months.

These cups are being used by nearly all first class engine builders East, where more than 10,000 of them are in use, and though they have been but recently introduced on this coast they can be seen at work on the engines of the Union Iron Works, Messrs. Prescott, Scott & Co., and in many other of our leading establishments. Any kind of oil can be used in them, but we suppose it is very generally understood now that a regular cylinder oil is best.

Tatum & Bowen, 329 Market street, are the agents for this coast, as they are also for the Albany cylinder oil, and Albany lubricating compound and cup.

General Revival of Mining.

On this coast there has been a genuine revival of mining this year. In several of the old mining counties of California the business had fallen into decay, and beyond a little scratching in gravel deposits and placers the industry had ceased to exist. A few months, less than one year, has worked a marked change. The revival of the important industry has extended not only to placer and gravel properties, but it has reached the long neglected quartz interest. Old claims have been revived, and new and important discoveries made; and the promise is good for an immensely increased product of gold during next year. The revival has been equally as extensive in the States of Nevada, whose chief industry at present is silver mining. This change is most marked upon the great Comstock properties. Never since the discovery of this splendid vein some 20 odd years ago have operations been so stupendous or so systematic. While the work has been beset by apparently insurmountable difficulties, such as grow out of great depth and the enormous volume of mainly hot water, they have been met and overcome by the experienced engineers of the Comstock. They have placed machinery on their mines of phenomenal power, and an intelligent and practical system of ventilation is progressing, which has reduced the sweltering atmosphere and made a fair day's work the rule. In Colorado the bulk of the population seems to be devoted to prospecting and mining, so great has been the impetus given to the industry since the extraordinary developments in Leadville, which for a time overshadowed the interest on this coast.

VISIBLE DROP FEED LUBRICATOR.

The mining region in Utah, in spite of the unfriendly attitude of the dominant factor in the population of the Territory, whose hostility was manifested directly by acts of concealment and misrepresentation for years, has been extended enormously during several years past. There is no longer any doubt as to the mining future of Utah. Some of the most productive mines on the coast are in that neglected Territory. We need only mention the Ontario, Horn Silver and Stormont, to say nothing of a number of lesser properties which are among the constant producers of bullion. Utah to-day is not half prospected; but the signs are rife of a largely increased activity, both in exploration and mining. In the northern Territories of Idaho, Montana and Dakota, the revival of interest in mining, especially in quartz vein mining, is conspicuous. The papers published at the mining centers of those Territories teem with news of operations in mines and with accounts of new discoveries. Their product of bullion is already large, and is steadily increasing. To young men of energy and enterprise those northern Territories present an inviting field, in which doubtless many splendid prizes will be found. Though the last mentioned, Arizona is by no means the least

interesting of our mining regions. Already her mining districts are countless, and new discoveries are reported weekly. Her miners are not only discovering mines to the hand of the capitalist, but they are producing largely of gold and silver. The wealth acquired from her mines will be the means of advancing her agricultural and grazing interests, and will render the future State the fit abode of an enterprising population.

The renewed interest in the mining industry is not confined to the Pacific coast. They have been pushing discoveries of gold and silver in Maine and Arkansas, and now we learn that a degree of activity, amounting almost to a fever, prevails in several of the counties bordering upon the Adirondack mountains in New York. The *Tribune* of the 25th instant remarks that the "New York gold fever rages almost in the manner of what the Californians call the 'ultimate West.' Eight 'mines' were recorded yesterday in the Secretary of State's office. There are times when it becomes a simple resident of the interior to know 'farmer's gold' when he sees it, and to be on his guard against thrifty speculators." This hasty review of this condition of the mining industry throughout the country impels us to believe that it will be largely extended during 1881. Mining for gold and silver has always been fascinating. Apart from the intense pleasure of owning a paying mine; of seeing the hitherto sterile and worthless hill and mountain lands yielding ingots of the precious metals; necessity may compel a larger attention to the business of mining.

Our products of the staples this year have been enormous, and it will be puzzling to find an outlet for the heavy surplus at remunerative prices. The latest advices from both France and England say that the demand for our wheat will be less than last year. In neither country for a number of years has the home supply been so large. There will be less money for the wheat and cotton grower. These considerations will be likely to turn the attention of capitalists and the enterprising generally to the great and productive industry of mining.

PEAT UNDERLYING HAYES' VALLEY.—At the last semi-monthly meeting of the Academy of Sciences, an interesting discussion occurred over the discovery of vegetable peat in an artesian well in Hayes' valley. In boring this well to the depth of 60 ft. plus, the work passed through three or four different strata of peat, each layer being about six inches thick. Specimens of this peat had been thoroughly tested by Mr. C. D. Gibbs, and presented to the Academy. He reported the peat as more or less impure, but excellent for fuel; it burns freely, and leaves a brown ash. The point discussed by the members was, whether this peat, which is unmistakably a vegetable formation, was situated below the ocean level, and whether it revealed a subsidence of the earth's surface at some remote time; or, whether it disclosed simply a deep boghole, which had been gradually filled by the ever-shifting sands of the ocean boundary of this peninsula. It is worthy of mention that Mr. Gibbs is preparing a map and diagram of the various underlying stratifications of this city, and will read a paper on the subject as soon as he shall obtain fuller data. He earnestly requests all artesian well-borers to preserve some samples, or record, of their borings at various depths, and forward them to him, and thus assist in completing a very much-desired geological map of our peninsula. He has already classified over 200 specimens of such borings, and more are needed, especially in some localities.

EXHUMING A MONSTER.—A dispatch from Chicago, Aug. 24th, says that while some laborers were excavating for a sewer in the north-western part of the city they came upon the remains of a mastodon at the depth of 18 ft. below the surface. Among the pieces already secured are a section of the task, 4 inches in diameter at one end and 6 inches at the other, and a tooth weighing 6 lbs.

THE MILWAUKEE & ST. PAUL AND CHICAGO & NORTHWESTERN RAILROADS have obtained permission from the friendly Sioux to cross their reservation on the way to the Black Hills.

CORRESPONDENCE.

Wearmit, unendorsed, opinions of correspondents.—Ems

Something of Bodie District—No. 2.

EDITORS PRESS:—The leading mine of Bodie bluff and one among the most productive on the coast, is the Standard Con. As has already been stated, it has yielded its millions; and judging from the very large ore bodies still in sight, may be expected to produce many millions more.

The next in order of production on the bluff and in the district is

The Bodie Consolidated.

This mine is about as well known as the Standard, and may likewise be dispatched with a very few lines. Its dividends have been numerous; its shipments upwards of \$2,000,000; greatest vertical depth, 625 ft.; has from 7 to 8 months of ore supply, and still sinking on the vein, which continues to average fully as well as in the upper levels. The ledge dips to the east; is said to give every evidence of a true fissure; is now essentially silver-bearing and exhibiting other characteristics of the Comstock. The Bodie Con. and the Mono are on the eve of sinking a joint shaft from 800 to 1,000 ft. east of present works—a line of policy that might be followed with advantage by other companies. Their machinery will be ample for a depth of 2,000 ft.

The Jupiter

Has reached a depth of 600 ft. A winze from the 500 level to connect with the main south drift on the 600, finds a regular two-foot ledge all the way down, with an average of ore varying little in value—the last assays running from \$20 to \$160—the ore extracted being estimated at from \$75 to \$100 per ton. Some very rich quartz was found along the footwall, one assay going to \$150 gold and \$4,300 silver, giving a little forecast of the rich strike in the south drift of the 600 level, mentioned in one of your late issues. The fine ore of the 500 level had been known for some time, and expectations had run high as to finding a larger body of this richer ore below. This late development, in the light of its comparatively great depth, and taken in connection with other recent discoveries, will be likely to infuse some new life into stockholders and give another impulse to prospecting.

The Double Standard.

In this vicinity, has a shaft of 307 ft. and winze from foot of same on the ledge of 80 ft.; width, from 2 to 3 ft.; the ore has given assays as high as \$300.

The Belvidere

Has made some little progress below the 550 level. The apex of an ore chimney was struck at a depth of 170 ft. The ledge gradually widened from this point downward, varying on the 300 level from 2 to 5 ft., enlarging to 6 ft. on the 500, and to 9 ft. on the 550 between walls—ore of rather high grade from 4 to 6 ft. wide on the levels successively. Over 500 tons have been broken down, and the Syndicate mill, with a capacity of 45 tons per day, can be more than supplied with good milling ore from the different levels. On the winze level below the 500 nothing has as yet been done, the rich ore there developed remaining intact, awaiting the completion of the station on the 550 level; meanwhile, the work of sinking, drifting, stoping, extracting and crushing goes on steadily and simultaneously.

Some mention should have been made at this point of

South Bulwer,

Which is situated in a good neighborhood, west of the Mono and south of the Belvidere; but notes of this and two or three other mines have been mislaid.

The Con. Pacific.

Located west of the Belvidere and Standard mines, embraces an area of 1,400 by 400 ft. wide; greatest depth by double-compartment shaft, 600 ft.; stations opened on the 400, 500 and 600 levels; on the 400 a large four-ft. vein was cut and drifts run north and south; ore of rather low grade, from \$10 to \$15 per ton. Another vein of 2½ ft. was cut 40 ft. east, partly filled with quartz worth \$25. On the 500 level east of station the same vein was encountered—here from 6 to 7 ft. wide—the ore from \$15 to \$40 per ton; and also the other vein of 4 ft. in width—quartz of about the same grade as on the 400 level. The company is now running from 600 station to cut these ledges, where a still greater improvement is expected. At a distance of 300 feet north of shaft a tunnel was run north 250 ft., gaining a depth from surface of 100 ft., from which point ledges Nos. 1 & 2 were soon struck, where 100 tons yielded at the rate of \$46 per ton. Winzes were then sunk on the lodes 265 ft. for developing ore the entire distance down. Work will soon be projected from main shaft, by drift, to penetrate the ore bodies, when extracting will commence.

The Bulwer Con.

Consists of 2 ledges, the Ralston or east vein, on the 400 level from 2 to 4 ft. wide, and the Stonewall, 4 ft. at same depth. The ore generally of rather low grade (\$10 to \$20 per ton), the east vein showing some improvement southward.

A winze was sunk 100 ft. from this level (400), where stoping has been commenced, and from which is now being extracted some of the rich-

est ore yet found, indicating larger and more concentrated bodies of ore, as well as of a better quality at greater depths. No crosscutting has been done from bottom of winze, and with the exception of a crosscut now being run from the 700 level of the Standard shaft to tap both veins, this is the only excavation below the 400 level. The total of bullion shipments of mine to date may be set down at \$350,000.

They have any amount of ore above the 400 to keep their mill running for a long time, and with present milling facilities may be able to produce the ensuing year from \$400,000 to \$500,000, but dividends can scarcely be expected before reaching the 700-ft. level.

The Tioga.

Shaft 860 ft., well timbered with square sets; several veins cut. The Yerington on both the 200 and 300 levels, has 4 ft. of good milling ore, and (No. 3) on the 500 ft. averages 2 ft., also of good ore. From lateral drifts on the veins, 400 tons have been extracted and in readiness for the mill. As no stoping has been done, a very large amount of ore is in sight.

The apex of a large silver vein 74 ft. wide has been cut from the 800 station, somewhat broken and mixed with vein porphyry, the ore giving assays from \$5 to \$125 per ton, which may be looked upon as a very promising development. The force is at present concentrated in sinking with the view of opening another level at the depth of 900 ft., where they anticipate finding a much richer and better defined ore body. The Blackhawk on the 220 level has a 4 ft. vein of fair milling ore, on the 320 a 6 ft., but ore not so well concentrated, and in crosscutting east and west from the 700 ft. or lowest level passed through several small veins, one of 3 ft. with well-defined walls, but without any material change in the quality of the quartz.

The Bechtel

Has two well-defined veins; the east, averaging two and one-half ft.; the west, on which a drift was run from old shaft 700 ft. to the south line of claim, is full five ft. in width. Some ore from the northern part of the mine was worked with a profit; that from the south end is of higher grade, running from \$25 to \$30, mill process; total of shipments to date being a little upward of \$70,000, and sufficient ore in sight to keep their (contemplated) mill running at its fullest capacity for two years or more after it is built. A new shaft has been sunk 300 ft., making connection with old works at a point 180 ft. north of south line. The company is erecting hoisting machinery, with a capacity equal to sinking from 1,500 to 2,000 ft., consisting of double engine 120-horse power and 60-inch boiler; four and one-half inch flat cables; reels so constructed as to obviate the necessity of moving the engine to either clutch or unclutch, thereby avoiding any possibility of any accident occurring.

The Syndicate,

Located on the north side of Bodie bluff, consists of two claims, each 600 ft. wide by 1,500 long, and covers several ledges, the principal one 48 ft. in width, and running the entire length of the property. The mine is opened by a shaft 550 ft., drifts and tunnels, the main and longest 2,500 ft., and 700 ft. below the surface at its terminus, at which point a shaft is being pushed down 200 ft. further with the view of crosscutting the ledges. The ore is represented to be all free milling, and a large quantity has been crushed, yielding an average of \$20 per ton.

For reasons previously stated, a few good mines have received no mention; others have been necessarily omitted for want of space. Let the above suffice. A. C. K.

GOULD'S COMET.—Prof. Klinkerfues, of Göttingen, Germany, has published a paper on Gould's comet, discovered in last February at Cordoba. His object is to point out that the probable identity of this comet with those seen in 1843 and 1668 need not be rejected because it does not appear to have been seen, although so conspicuous an object, between those years. So nearly does it approach the sun (within, indeed, about 100,000 miles of its surface) that the resistance to its motion when at perihelion is likely to be sufficient to produce a very considerable diminution in its periodic time, the case being, in fact, one of resistance from the sun's atmosphere itself, and not merely, as has been conjectured in the case of Encke's comet, from an ethereal medium presumed to exist within the orbits of at least some of the planets. Hence there is nothing extravagant in the supposition that the resistance of the part of the corona within which the comet passes may be quite sufficient to diminish its period of revolution from 175 years to 37 years. Carrying this view still further back, Prof. Klinkerfues contends that it is probable that the same comet may be identical with one seen and described by Aristotle in the year B. C. 371, when that philosopher was only 13 years old and still living in his birthplace, Stagira. He considers it likely that while the period of revolution from B. C. 371 to A. D. 1668 was 2039 years, it was diminished by the resistance of the sun's atmosphere, first to 175 and then to 37 years; and further, that it has at the late passages through perihelion been again decreased to 17 years, so that it may be expected that the comet will return in the autumn of 1897.—*Iron Age.*

A HARTFORD inventor has nearly finished a road carriage, to be propelled by compressed air. The compact machinery is under the rear axle, a reservoir holds enough of air for a run of many miles, and the steering is simply done,

Microscopy and Forgery.

A paper on "The Detection of Forgeries by the Microscope," read by Prof. J. N. Wythe, A. M., M. D., before the Microscopical Society: An article in the *Bankers' Magazine* for August, 1878, refers to the value of the compound microscope in the examination of handwriting, beyond the ordinary methods of experts who rely upon unaided vision or a hand-lens. It shows that the conclusions of an ordinary expert are reliable just as far as they rest upon data which can be explained, and no farther. A man who writes his signature frequently falls into a series of rhythmic movements which are peculiar to himself. This may arise from habit, or individuality of muscular organization. His general handwriting may differ in style from his signature, but the accentuation remains the same. A talented imitator may produce this general rhythm of a signature, and cause the testimony of an expert to become vague and uncertain. The expert may detect a difference, empirically, but he is unable to explain it.

To the Satisfaction of a Jury.

"It is just at this point" says the writer, quoting from a letter to the *New York Times*, "where the methods of the expert break down, that the more delicate methods of optical analysis, represented by the compound microscope, interpose to detect and demonstrate forgery." In addition to the larger rhythm upon which the expert bases his judgment, there is a minute secondary rhythm caused by the action of the small muscles in regulating the amount of pressure upon the pen, which is imperceptible to the naked eye, and cannot be accurately determined with a simple magnifier, but which is easily discerned in a compound instrument under a power of about ten diameters, if the writing is strongly illuminated with a good bull's-eye condensing lens. These variations of pressure are between 200 and 300 to the inch, and are regular in proportion, as they are spontaneous and involuntary. When a man writes naturally, the pressure variations are rhythmic, while on the contrary, when he is consciously imitating the writing of another, they are irregular and unsymmetrical. No matter

How Cleverly a Signature May be Imitated.

So long as the writer exercises the voluntary control of the hand, which is essential to the act of imitation, just so long the margin of the stroke can be demonstrated optically to be irregular in the length and the distribution of the waves which indicate the muscular impulses. Thus the compound microscope determines the issue at the point where the coarser processes of the ordinary expert fail. My attention having been called to this subject, I instituted numerous experiments, which have convinced me of the general accuracy of the article, of which the foregoing is an abridgement. Careful investigation enables me to classify the phenomena of hand writing, especially signatures, as analyzed by the compound microscope, as follows:

1. The rhythm of form, dependent on habit or individual organization. This is the main dependence of the ordinary expert. It may be determined by the naked eye or a hand-lens, but is still more easily seen by means of the magnified image in

The Compound Microscope.

In some cases, an enlarged photograph of genuine and deputed signatures may be useful—remembering, however, that the form of letters may change, from time to time, more readily than the general rhythm.

2. The rhythm of progress. This is the involuntary rhythm, referred to above as pressure variations on the point of the pen, and seen as a wavy margin to the letters of signature when well illuminated on the stage of the compound microscope. It is caused, in all probability, by the rapidly successive nerve impulses upon which the contraction of the muscles depend. In age or infirmity, these impulses are perceptible to the eye, and we say that the hand trembles. "But as a matter of microscopic analysis the hand always trembles, and it is an inalienable property of muscular contraction that it should." The regularity of this rhythm is destroyed by a voluntary effort at imitation, and is somewhat interfered with, but not entirely broken, by mental excitement. This rhythm differs in different hand-writings, so that it is well for the examiner, if practicable, to accustom himself to the habitual rhythm of a genuine signature before expressing a judgment on one which is questioned.

The Art of Writing.

Is a most complicated one, requiring the simultaneous action of many muscles. When perfectly performed it should be nearly, if not quite, automatic, requiring very little mental stimulus for its performance. If any act which should be automatic, demands our attention in order to execute it, the difficulty of performance increases. The ordinary mental stimulus suffers an emotional diversion, which causes proportional muscular impotence. Hence emotional disturbance causes a trembling handwriting. In cases of writers' cramp, in which the muscles respond but sluggishly to the will, and render the grasp of the pen faltering and uncertain, this rhythm is greatly exaggerated or interrupted. Paralysis of the ulnar nerve, rheumatism of the shoulder or wrist, neuralgia and alcoholism, may also interfere with the rhythm of progress. But in no case is the failure of the rhythm so marked as in a voluntary attempt at imitation.

3. The rhythm of pressure. By this I mean,

not the involuntary and rapid action of the muscles, producing a microscopic wave as the writing progresses, but a rhythmic alternation of light and dark strokes, which is

Characteristic of some Signatures.

And which, in all probability, is a variety of the rhythm of form; yet, as it is revealed to microscopic analysis rather than to ordinary vision, it may escape the most expert imitator, and so become another factor in making up a judgment in any case.

If the microscopist carefully observes these three rhythms, being careful of the illumination of the letters, he cannot fail to demonstrate the difference between genuine and an imitated signature.

In a recent trial before Judge Crane, in Oakland, I was able to discriminate between imitated and genuine signatures in a large number of cases of remarkable similarity, prepared by a most talented writer, as well as to testify to the genuineness of signatures in which there was

Considerable Variation of Form.

Mr. Geo. C. Hickox, also a member of the Microscopical Society, and well known as an expert in such matters, when his attention was called to this use of the compound microscope, declared to the Court that it was a new and wonderful revelation fixing beyond question the individuality of hand-writing, especially of signatures.

Should this method of investigation be much used, as it ought to be, it would be convenient to have a microscope made for the purpose, having a large stage with clips so as to hold paper of considerable width, a tube of wide diameter to collect as much light as possible, a very low power eye-piece, and a special objective of long focus and large field of view.

CLEAN, THEREFORE HEALTHY.—The Board of Health and the Police Commissioners should study the report Dr. Trowbridge, the United States Consul, sends from Vera Cruz to New Orleans. The death rate of Vera Cruz is now less than during any of the previous years of his 11 years' residence in that city. There has not been a known case of yellow fever or smallpox during the year 1880, and he reports the fact as an encouragement to commerce. And this is the way he explains the healthfulness of Vera Cruz: "I do not expect to be successfully contradicted when I say that this is one of the cleanest cities in the world." And this is the way he explains the cleanliness of Vera Cruz: "Vigilant officers of the Board of Health, assisted by the authorities, have labored intelligently, and have kept the city clean." His report illustrates the truth of our assertion that New York's excessive mortality is the direct product of the filthy condition in which the Police Commissioners permit our city to remain. His statement that officers of the Board of Health have labored intelligently to keep Vera Cruz clean, must seem a reproach to the members of the Board of Health of New York, who have not so much as officially protested against the slaughter of more than 12,000 persons a year permitted by the Police Board. Would vigilant officers of our Board of Health labor intelligently to compel Police Commissioners to keep the city clean, New York would soon be known as the cleanest city in the world, and therefore the healthiest.—*N. Y. Evening Mail.*

WHO FIRST FOUND GOLD.—I have talked with a dozen old pioneers, some of whom were with Marshall or Sutter at the time (Marshall was at Coloma, and Sutter at New Helvetia), and have endeavored to learn the true secret of the Find, but without success. Some of them say that Marshall found the first piece of gold; others that his little daughter found it; others, that Mrs. Winnier, who provided meals for the workmen at the mill, found it; and others, again, that Mrs. Winnier's son found it. Gen. Sutter himself once told me that Marshall was the finder, and, although Sutter was not on the spot at the time, I am inclined to believe this the true story; for, while still fresh, it must have been related to Sutter with great minuteness. It is, however, agreed on all hands, that, if Mrs. Winnier did not find the gold, she was the first to determine its character. Woman-like, she put the doubtful nugget into a soup-pot, and boiled it. The result of that assay was to affect the fortunes of millions of people. Among others it affected Capt. Sutter, for it made him a beggar.—*Alexander Del Mar in Californian for September.*

AN INTENSIFIED ELECTRO-MAGNET.—Dr. Stone recently exhibited before the Physical Society a very interesting electro-magnet of novel construction, and based upon a principle which will probably be applied with advantage in the construction of electro-magnets for dynamo-electric machines and telegraphic apparatus. It is known that electro-magnets enclosed in jackets of soft iron are far more powerful than when the copper coil of wire is unenclosed. The iron jacket has the effect of exalting the magnetic power of the poles. Dr. Stone does not employ a soft iron jacket, but instead of using copper wire to wind the bobbins, he uses best charcoal annealed iron wire about one-fifth of an inch in diameter. Four wires are wound on in parallel circuits, and the current is split up among them in "multiple arc." They are insulated from each other by paraffine wax. By this felicitous arrangement the lifting power of Dr. Stone's large magnet is, with a battery of four or five Bunsen cells, increased fourfold.—*Engineering.*

MECHANICAL PROGRESS.

Economical Cut-off in Steam Engines.

Theoretically the most economical cut-off is readily seen to be that by which the steam at the instant of release has, in the particular cylinder, and under the particular conditions, no capacity for developing further work.

In a cylinder of indefinite extent, having one fixed head and a moving piston between which steam has been admitted to a certain point, then cut off and expanded, the best point theoretically at which to release the steam will be where the pressure has fallen by expansion to the back pressure. This is evident from the fact that up to this point there is an effective pressure upon the piston to urge it forward, while beyond this point the effective pressure is backward, or prejudicial. An indicator card taken from an engine working under these conditions will have a sharp point at the end, or termination of stroke. If the atmosphere is the back pressure, as in case of non-condensing engines, then the release occurs where the expansion pressure equals the atmosphere. In condensing engines it is where the expansion pressure equals the pressure of the condenser, where the back pressure is zero, if possible, it is where the volume of expansion is infinite. For this latter case the above ideal cylinder must be of infinite length.

For all the above cases, the ratio of expansion is equal to the pressure of admission divided by the back pressure, where Mariotte's law of expansion holds; since, by this law, initial pressure \times initial volume = final pressure \times final volume. Or,

$$\frac{\text{initial pressure}}{\text{final pressure}} = \frac{\text{final volume}}{\text{initial volume}} = \text{ratio of expansion.}$$

This result agrees with that obtained analytically by Prof. Wm. D. Marks in the June number of the *Journal of the Franklin Institute*, where the simple rule for finding the most economical point of cut-off, stated in words as that by which the terminal pressure must equal the back pressure, was looked for without success. According to this rule the indicator card shows at a glance when the specified adjustment is realized.

This adjustment of the cut-off is pretty generally accepted by engineers as the best theoretically. But in actual steam engine practice the adjustment will be quite different, for several reasons, such as excessive size of cylinder, causing loss by radiation of heat and cooling by expansion, friction by mechanism, undue strains of parts or increased piston speed, etc. For instance, the size of the crank pin enters into the problem. In practice, the indicator diagram from an engine running under the most favorable conditions, or with the most economical practical cut-off, should show its narrow end cut square off with some considerable breadth, instead of being absolutely sharp; and what breadth it should have is a matter not easily determined. To illustrate, take an example of a non-condensing engine working under 90 lbs. absolute pressure of admission per square inch, cutting off at one-fourth the stroke. The terminal pressure will be seven and a half lbs. above the atmosphere, Mariotte's expansion; but if the cylinder were 50% longer, the terminal pressure would be just the atmospheric, or that required by the solution given by Prof. Marks. The gain in work done per stroke, for the 50% longer cylinder, will, however, be, as found by calculation, less than 4% of the work done without 50% added.

To save this 4%, the engine, for a given establishment, would require to be one-half larger, making the same number of strokes per minute. Or, if the number of strokes diminish with increase of size, it would need to be more than a half larger. Aside from the considerations of greater loss of heat by radiation, cooling of steam, friction, etc., there comes the interest to be paid on the additional investment required in the larger engine. In the light of considerations like the above, which must be familiar to professional as well as practical engineers, it would seem that the qualifications needed to the last sentence in Prof. Marks' article must, through some hurry or otherwise, have been overlooked, but which, it is hoped, will be fully supplied in the article promised soon to follow.—S. W. Robinson, in *Journal of Franklin Institute*.

A CAR ON RUNNERS.—A car has been patented with skates instead of wheels, intended for elevated railroads. It uses grooved instead of T rails. The primary object of this device is to avoid the deafening roar of the cars in passing through such streets as those in the city of New York. The rapid rotation of the wheels causes the rapid vibration of the whole framework of the road, thereby making the noise and tending to loosen the rivets and shake down the superstructure; all of which would be obviated by the skates and the special rails. This special rail should be of polished steel, presenting an edge of three-eighths of an inch surface. The skate need not be over 30 inches long; and the lubrication of grease (not oil) should be the least possible. Experience alone can demonstrate the best adaptations and adjustment, as in the case of all new inventions.

Furnace-Shield.

The intense heat to which "boilers" are subjected in rolling mills, while puddling their heats, is well known, and is generally urged as one claim for extra high wages. The manager of the Sligo Iron Mills, Pittsburgh, has recently invented and applied an ingenious contrivance, by which heaters and puddlers are protected from the fierce heat, and partly also from the intense glare of the molten metal of the furnaces. The apparatus consists of a movable hollow apron or shield of sheet iron suspended in front of the furnace by means of hangers provided with pulleys, which run on a track-bar, so that it can, by means of handles, be easily and quickly pushed aside when it is required to charge or draw a heat. The shield has an arched opening in its lower part, which, when the shield is in position, comes directly in front of the stopper or working hole of the furnace; the sides of this opening being beveled, the usual range of lateral motion required for the puddler's tools is not interfered with. The shield is constantly supplied with cold water, which is introduced at the top, and after running through it is drawn off by a pipe leading to the hosh of the furnace, the water thus serving a double purpose. An air-chamber is arranged at the top of the water-space of the shield; into this chamber air is forced, which having been exposed to the cooling action of the water flowing through the shield, passes into an air-distributing pipe running along the top and in front of the shield. The ends of this pipe are closed, and at its lower side it is perforated and provided with a series of short tubes, through which the cool air is discharged in jets upon the workmen in front of the furnace. The utility of this furnace attachment will be readily understood when it is stated that the shield is a perfect non-conductor of heat, the outside face being always of the same temperature as the water passing through it. It thus effectually protects the workmen from the intense heat of the furnace, enables them to get out their full number of heats and cools off the surrounding atmosphere.

AVOIDANCE OF VIBRATION IN MACHINERY.—We have already made allusion in these columns to the avoidance of vibration in machinery, by the use of asphalt, and now we have an elaborate paper on the subject, read by Mr. W. H. Delano, before the British Institution of Civil Engineers, in which he spoke of the use of asphalt for the foundations of machinery, notably for those running at high speeds, the asphalt having the valuable quality of absorbing vibration. This was instanced in the case of a Carr disintegrator, which, being mounted in a pit lined with bituminous concrete, was worked at 500 revolutions per minute without sensible tremor, whereas with the former wooden mountings on an ordinary concrete base, the vibration was excessive, and extended over a radius of 25 yards. At the Paris exhibition of 1878, there was shown a block of bituminous concrete, weighing 46 tons, forming the foundation of a Carr disintegrator, used as a flour mill, and making 1,400 revolutions a minute, a speed which would have been impracticable on an ordinary foundation. Extensive applications of the material for this purpose are made in France, especially in connection with steam engines and steam hammers.

SMEETING IRON SAND.—It seems, says the *London Times*, that the New Zealand iron sand, as taken from the beach, is mixed with an equal quantity of clay and of the ordinary sea-sand, which contains a large admixture of shell; these materials are worked up into bricks, which are hardened in a kiln, broken up into regular pieces, and smelted in an ordinary cupola furnace. The product of this simple process is cast steel of the finest possible texture, from which some beautiful specimens of the finest cutlery have been manufactured. These experiments were conducted by a mechanic in the government employ, who was restricted to an expenditure of £100, and was therefore only able to erect a furnace of the most temporary description; he, however, succeeded in producing, at the first and only trial, 500 weight of steel in the manner described above, and his success seems likely to lead to further and more extensive efforts to utilize the almost inexhaustible deposits of this ore which exist at Taranaki and elsewhere.

NEW DEPARTURE IN LOCOMOTIVE BUILDING.—A rather curious looking locomotive is in course of construction at Waterson. The machinery will be on top of the boiler, instead of under it, as usual, and the boiler will hang very low on the wheels. There will be two pairs of driving wheels, but instead of having them follow each other, one pair will be on top of the other. The real driving wheels will be the upper pair, and they will turn in the opposite direction from that which the engine is going.

TO PREVENT THE HEATING OF JOURNALS.—Von Heerin proposes a method of preventing the heating of journals by a mixture of sulphur and oil or grease. The fine metal dust formed when a journal runs hot, and which strongly acts upon both journals and bearing, forms a sulphide of sulphur. This compound, which grows soft and greasy, does not cause any appreciable amount of friction. It has been very successfully used by the steamers of the North German Lloyd.

SCIENTIFIC PROGRESS.

The Atmosphere in the Early World.

The deposit of carbon during the palaeozoic age was enormous, requiring a correspondingly long time, because, owing to the great amount in the atmosphere, so much needed to be removed before any sensible effect upon the temperature was produced. During the mesozoic, there being less carbonic acid in the atmosphere, a shorter time sufficed to produce an equal effect. For like reason, the change of temperature during the tertiary was more rapid until about the close of that period, after which no further change occurred, the elimination and supply of carbonic acid seeming to have become equal. Closely allied to the question as to the length of the geological divisions, and in its explanation identical with it, is that which asks why there was so great a difference between the duration of the earlier and later types of life. The length of a geological division is really the length of a certain type of life, and that which accounts for the one accounts also for the other. The facts which have been considered, viz., the abundance of coal and lignite, both certainly of vegetable origin; the smallness of the amount of CO₂ which have been derived from volcanoes; the universal warmth; the present non-existence of the early species; the almost total extermination of species at the end of each of the geological ages; the absence of arctic cold, or other sufficient cause for such extirpations; the appearance of new species, and these always in the direction of progress towards present conditions; the great disproportion between the length of the earlier ages and the later, and the disparity in the duration of the corresponding types; the world-wide extent of these phenomena—all these are in harmony with an atmosphere richer in carbonic acid than the present that they seem to demonstrate its existence. How much carbonic acid there was at first in the atmosphere it is impossible to determine. It now forms only three or four ten-thousandths of the whole. Forty or fifty times that amount would very decidedly affect temperature, partly by its own influence, and much more indirectly, by increasing the capacity of the air for water. One hundred times would increase the warmth somewhat more; but if, after that, ten or twenty times that amount were added, the temperature would be scarcely affected, while the effect upon the flora and fauna of the period would be of the most decided character. In the azoic time the amount of carbonic acid in the atmosphere must have been enormous.—*The Penn Monthly*.

Dust Showers.

M. Dauhree has given an account of the dust showers that were observed from the 21st to the 25th of April, 1880, in the departments of the Lower Alps, Isere and Ain. Heavy dark clouds, resembling a dense yellowish mist, traversed the valleys during the day, depositing a reddish dust with a little water. The neighboring mountains were covered with snow, which assumed a rusty hue to the height of about three kilometers (1,864 miles), and above that height it remained white. The snow, upon melting, left a deposit of a yellowish brown color, a little redder than limonite dust and almost impalpable. When heated in a tube it blackened, with a disengagement of water and some organic matters of a strong odor. With dilute chlorhydric acid it effervesced strongly, showing a considerable proportion of carbonate of lime. Boiling chlorhydric acid destroyed the yellow color and left a residuum which was fusible under the blowpipe into a white globule. This residuum contained numerous flakes of white and colored mica, together with some particles which appeared to be feldspar. None of the particles were attracted by the magnet, so that the dust was not probably cosmic, but it resembles in its structure the sand of Sahara. P. de Jussieu reports a similar shower at Autun, on the 15th of April, in which there were traces of iron and perhaps also of lead. A shower occurred in Sicily on the 10th of April, which is said to have deposited considerable quantities of metallic iron covered with a thin layer of oxide. Prof. Orazio Silvestri, of the Meteorological Institute in Cantania, gives an account of a shower during the night of March 29th—30th, in which the dust contained particles of iron, small infusoria and organic molecules. Some of the particles were spherical, as if they had been melted.—*Comptes Rendus, Fortsch. d. Zeit.*

CRYSTALLINE FORM OF MAGNESIUM.—Des Cloizeaux has examined some beautiful crystals of magnesium, which were presented to the French Academy by M. Dumas. The crystals were obtained by sublimation and are of a white color, with the brilliancy of silver. Their faces are often curved and the edges blunt; the usual form is that of a regular hexagonal prism, terminated by a base which is a little less brilliant than the lateral faces. The edges of the base are often replaced by an annular truncation, the combination of which with the faces of the prism recalls that of tellurium crystals. The culminating angle is more acute than in the other rhombohedral metals—arsenic, tellurium, antimony and bismuth. The crystals are very malleable and sectile, but without visible cleavage.—*Compt. Rend.*

Metallic Deposits on Glass.

Herr Carl Mann describes a new method for producing a brilliant metallic deposit on glass, as follows, his object being to substitute the cheapest sulphides of antimony and lead for silver: When nitric acid is added to a concentrated aqueous solution of tartar emetic solution as long as a precipitate is produced, then filtered, and the precipitate stirred into fresh water, the liquid formed is essentially a basic nitrate of antimony in suspension. On diluting a portion of this milky liquid and boiling, the precipitate dissolves in the hot acid liquid. If a little of this hot solution is poured into a hollow glass vessel and cooled as rapidly as possible by shaking or holding it under running water, the liquid becomes milky and deposits a very thin film of the antimony salt on the sides of the glass. On washing it out with cold water and passing sulphuretted hydrogen gas into it, or pouring in a solution of the gas, the glass appears of a uniform faint yellow color; the sulphide of antimony formed adheres very firmly to the sides of the glass after washing and drying. By repeating this procedure several times, the film can be increased very considerably within certain limits. Such glasses appear of a beautiful golden color, with a green reflection. If sulphuretted hydrogen gas be passed into an aqueous solution of oxide of lead in an excess of metaphosphoric acid, a portion of the sulphide of lead will, under proper conditions, adhere firmly to the sides of the vessel in which it is precipitated. The vessel will then have different metallic colors by reflected light, according to the thickness of the film, and darker when thicker. By transmitted light such a glass has a yellowish-brown color. The lead solution may be prepared by dissolving 1 part phosphoric acid in 4 parts of water; also a second solution of 1 part sugar of lead in 20 parts of water, and a third of a strong decoction of sassafras, or an aqueous emulsion of an ethereal oil, such as turpentine. To cover a glass ball with this lead film, three volumes of the phosphoric acid solution are poured into the ball, then four or five of the lead solution, and as much of the sassafras solution. The total quantity of the liquid must be sufficient to easily cover the interior on tipping it slightly. If a thin film of the antimony be deposited first, the lead film adheres better. The sulphuretted hydrogen gas is passed in, and the vessel kept moving, to bring it in contact with every part of the glass. It is afterwards washed and dried.

WEATHERING OF STONES.—In a paper read by Prof. Geikie, before the Royal Society of Edinburgh, the author records the results of certain observations on the weathering of tombstones and monuments in graveyards, with a view of measuring approximately the rate at which atmospheric degradation takes place under natural conditions. The calcareous rocks (marble and limestones), as might be expected, yield quickly as a rule to atmospheric agents. In some cases slabs have been worn down a quarter of an inch in less than a century by the superficial solution of rain containing carbonic and sulphuric acids; in others they are found to have been disintegrated internally, so that the very substance of the marble crumbles away; and in a third series of cases, where the slabs have been inserted in a framework of solid stone, the expansion of the slabs has caused outward curvature and ultimate fracture. In sandstone the effects are more varied. Where the stone is flaggy or distinctly bedded, and the lamination is exposed to the action of the rain, or where the rock is not of homogeneous composition, the destruction has been very rapid, the flakes scaling off and leaving a raw, bare surface. Slabs of freestone and other unlaminated sand rocks Prof. Geikie, however, finds to be so enduring that the sharpness of the cut letters is scarcely blunted in the slightest degree by a century's exposure.

EFFECT OF POLARIZATION UPON FRICTION.—Herr Koch has made an interesting experiment showing the effect of polarization upon friction, the result appearing to have a bearing on the action of the Edison friction telephone. When a plate of platinum or palladium is polarized by means of an electric current, the friction of these metals against a plate of moistened glass increases immediately. To measure the friction, Herr Koch uses the metal in the form of a hemispherical button resting on the bottom of a glass cup filled with pure or acidulated water. The button serves as a pivot to a magneto needle, which oscillates under the action of the earth; the decrease of the oscillations measures the friction of the pivot. Polarization is produced by the current of the Daniel element, one pole of which communicates with the metallic button, while the other terminates with a platinum wire entering the water of the cup. The polarization by hydrogen produces no effect, but polarization with the pole oxygenated is found very efficacious. The friction was increased, through this polarization, in the ratio of two to three, and sometimes in that of two to four. This increase of friction appears immediately after the circuit is closed, and disappears immediately when the current is reversed; but it disappears slowly, like the polarization itself, when the circuit is merely opened. Palladium behaves like platinum. Gold gave no effect.

GLADSTONE MINE.—Plymouth cor. *Ledger*, Aug. 21. This mine, 1 mile north of Plymouth, is being vigorously prospected. Rich specimens have been found now and then by hunters, in the surface croppings. The shaft is down 40 ft, but no ledge of importance has been met with. On the surface large boulders of quartz are seen projecting from the ground over 50 ft wide. The gouge in the shaft is rich in sulphurates.

PIONEER.—The tunnel of this mine is being re-opened. It is over 200 ft in length, and runs through hard slate. A well defined ledge, 8 ft wide, was discovered, the rock of which prospects well. Near the end of the tunnel it had cave occurred, preventing further operations without ample means. It is expected that this week the new company will commence operations.

NOTES.—Two astraras are being fixed up in the creek bed. They will be employed to grind the sand that comes from the mill. It is a good move, and one which I think will pay. There are many prospectors at work, and the town looks livelier than I have seen it for years.

SUTTER CREEK NOTES.—Cor. *Ledger*, Aug. 13: The new Mahoney 40-stamp mill is now being put together, and is beginning to assume somewhat the shape of a mill. The machinery is arriving every day—heavy shafting material, self-feeders, pulleys of different dimensions, etc. The mill will be being run on the rock from the Mahoney in a short time; it is to be hoped that we will bear the sound of 340-stamp mills in this town.

JACKSON NOTES.—*Ledger*, Aug. 21: In the Kennedy mine the middle shaft, to which operations are confined, is now clear of water, the hoisting machinery recently put in having taken it out in a very short time. This machinery is operated by water power, by means of one of Knight's wheels, and is a complete success in every respect. The construction of a small reservoir on the top of the hill, 10 inches will be sufficient to run the works. The shaft is 200 ft deep; at this depth a drift run west, and had just entered the ledge when work was suspended two years ago. It is to ascertain the extent and quality of this ore body that present operations are directed.

ITEMS.—The 10 extra stamps have been put into the Monticard mill, and the full 20 stamps have been kept running steady for 2 weeks past. Reports reach us that a ledge of paying quartz has been struck in the Morganti mine, at Hunt's gulch, within the last few days. At the Zeile mine the quartz appears to be improving in quality. The building of the sulphuret works is being pushed.

BUTTE.

MIOCENE GRAVEL CO.—Oroville *Mercury*, Aug. 20: Water is now running in the Miocene ditch as far down as the lime kiln, 13 miles from the fountain head. It is thought that the stream will be running into Coal canyon, 7 miles further this way, within three weeks—providing the lumber company keeps the flume free supplied with the necessary material. Should nothing occur to upset present calculations the company will be ready to begin work on the lower end of the ditch. The 30-inch pipe of 30-inch pipe, made from No. 4 iron, has been completed for the company by Brock & Taber, and the latter firm are now engaged in filling another order for 800 ft of 22-inch pipe made from the same quality of iron. All of this pipe will be used in the workings of the mine.

BANNER MINE.—The main shaft and levels have been cleared of water. The frame-work of the mill is in position and the machinery is being put up. It is expected that everything will be in readiness to crush rock by the 10th of September.

NOTES.—William Gregory bought \$7,000 in gold to this city, Wednesday. It came from the claim known as the Gregory & Welsh, situated on Table mountain near Oregon gulch. Three-fourths of the amount was in a block, the remainder being nuggets.

NIMBLEW DISTRICT.—Mr. J. K. Smith, just returned from this district, informs us that a company of Eastern capitalists have bought the famous Meredith mine, and intend to develop it thoroughly. Meredith and a companion took out some \$16,000 in 13 months and didn't have one-third of the gold, as Indians have picked nuggets between from one to three ounces each out of the tailings.

NOTES.—Mr. McSmith says there is more gold in that section of the county, yet undeveloped, than in any other portion of the State; he also states that there are at least one dozen ledges, situated within a half mile of the Meredith, equally as valuable as that deposit. He has a prospect of making it thoroughly. Meredith is now busy preparing for next winter's operations. This claim is promising big returns. Prospectors are not very numerous in the district, which state of affairs is probably owing to their ignorance of the existence of such an inviting field of labor.

GRAVEL STRIKE.—A very rich and extensive deposit of blue gravel has been struck by Woodson & Co., in a tunnel they are running at the forks of Butte creek.

NEW BUTTE MINING.—*Chronicle*, Aug. 18: Parties on Butte creek who own valuable claims which cannot be worked by the Shepard ditch, have located a new ditch, commencing about 200 ft below the Cherokee head dam, running down the west side of Butte creek and terminating at Centerville. The capacity of the ditch is to be 4,000 inches, and the new company have a capital of \$150,000.

CALAVERAS.

GWYN MINE.—*Chronicle*, Aug. 21: Very encouraging reports come to us from this mine. All the batteries are in full play and excellent rock is being crushed. No work is being done in the north levels at present. The rock is all taken from the south levels, where the quartz is remarkably rich. We are told that things never looked better at the mine than now.

WEST POINT NOTES.—The Eureka has made a final clean-up for the season. We have not been informed in figures of the amount realized, but from what we can understand it was an unusual clean-up, fully coming up to the expectations of the owners. A vast amount of gravel has been washed away, for the work has been vigorously carried on day and night during the whole season, and a large quantity of water—2 pipes playing continually—and a large force of hands, is the result of the 35ers. The gravel has been kept immediately upon the line, in a ditch with a view to completion before the rains set in, and also to put the claim in readiness for next winter's operations.

WEST POINT NOTES.—Cor. *Chronicle*, Aug. 15: We still keep going ahead with our mines. Everyone appears to look forward to the good times coming when West Point will be classed as one of the best mining camps of the State. The mine at Westfield, and the better of the 35ers, is the calorator of California. No idlers now, no idle mills, and the calorator of Our hydraulic are still working on the precious metal, and everyone is busy.

EL DORADO.

CALIFORNIA W. & M. CO.—*Mountain Democrat*, Aug. 21: Hon. Thos. Findlay, manager of the California water and mining company, informs us that greening is progressing satisfactorily on the new mill at Greenwood. The old system of hydraulicising seam mines was a failure or the simple reason that nine-tenths of the gold was carried away with the tailings. To pay, the vom-matter of the seams must be crushed.

PROSPECT FLAT MINE.—Lately there was a rumor that the mine was paying richly, and that the owner had been investigating this rumor. While we were not sure just what the mine is yielding, we find that the owners have let a contract for adding 10 stamps to the 10-stamp

and the demand for laborers is brisk,

Extreme Rarity of Premature Burials.

[Prof. William See, M. D., in *Popular Science Monthly*.]

A former article on "Premature Burials" in the *Monthly* asserted that, in effect, the ordinary physician is not capable of reaching a satisfactory conclusion upon the signs of death; and as the tendency of the article was to magnify the importance of the probabilities of premature burial in cases of trances and suspended animation, the writer has thought it proper to brief in what follows his opinion of the medical jurists of the present day upon this subject. The only motive in preparing this paper has been not to contradict the fact that premature burials may have taken place, and under the most unhappy circumstances, but to place renewed confidence in the ability of the ordinary general practitioner of medicine to recognize the distinction between a state of trance and a state of death, and to induce a disregard of the idle stories of ignorant and superstitious persons about premature burials.

In discussing this subject, how far are we justified in taking the statements of the earlier writers? The credulity of the public in similar matters is sufficiently shown in such works as Carpenter on "Mesmerism, Spiritualism," etc., and Hammond on "Fasting Girls," to induce us to view general statements with much suspicion. M. Fontenelle has published 46 cases of premature burial from the time of Plutarch downward. Taylor, from whose work on medical jurisprudence this article draws freely, after a careful examination of all these cases, rejects the greater number of them simply because they are drawn from such sources as to render them perfectly inadmissible as evidence. M. Carre, in 1845, published the assertion that 46 cases had occurred since 1833. Taylor examines his cases, and finds that no particulars by which their accuracy can be tested have been given. The whole subject, as taken from the tone of the article now commented upon, and from public opinion in general, resolves itself into two statements, viz., that it is quite possible, and has been proved, that a state of trances, prolonged and of a nature to simulate death, may exist and deceive even those whose daily avocations make them familiar with death itself; and that many cases are on record where changes in the position of the body, and even where the birth of children have taken place after interment.

For the existence of a trance state sufficient to simulate death, all appreciable movements of respiration and circulation must be suspended for a considerable length of time, and there is but one properly authenticated case on record as accepted by physiologists; even this case will not bear too close discussion at the present day. We are told in works on physiology that a Col. Townshend was able at will to suspend animation to the extent of obliterating any perception of the heart or pulse beat, and of any respiratory movement, as a mirror held over the mouth and nose showed no dimness of its surface; and further, that he was able to continue in this condition for the space of half an hour; at the end of this time gradually the signs of returning vitality began to assert themselves until a perfect restoration of the functions of life ensued. From the description generally given, we are led to suppose that this was done not once but several times, and that the subject was under careful inspection by medical men during the continuance of this state. But Braid, in his "Observations on Trance," tells us that Col. Townshend, as a patient of Dr. Cheyne, was in the last stages of a chronic kidney disease when, *nine hours before his death*, he made known to his medical attendants his conviction of an ability to "die or expire when he pleased, and yet, by an effort or somehow, he could come to life again." This he tried before Dr. Cheyne, with the result as just recorded. This case happened nearly 150 years ago, and, in view of its occurring only once and under such peculiar circumstances, with no details as to the extent and accuracy of the means taken to obviate all sources of error, leaves room for the skeptic, without casting a slur upon the good name and reputation of Dr. Cheyne, to express strong doubts upon its probability.

A case which has interested the medical profession very much and is of recent date, is that of the late Dr. Groux ("Proceedings of the Medical Society, County of Kings," Vol. III, p. 350 et seq.), in whose person there existed from birth an opening or fissure in the breast-bone (sternum) which he could extend by forcible separation to the width of two inches. He was supposed to have possessed the power to arrest the action of the heart at will—for a duration of about 20 seconds—but without any other disturbance of his usual condition. The arrest of the heart's action in this case is affirmed positively by some, doubted by others; one examination by three medical gentlemen developed no stoppage of the heart's action, but merely a stoppage of the pulse at the left wrist, attributed to the unusual mobility of the collar-bone (clavicle), by which the artery (subclavian) passing under it to the wrist was compressed.

Medical jurists, after carefully examining all evidence that can be accepted upon such cases, have concluded that it is impossible to suspend animation or to simulate the same, without detection by the ordinary means, for so long a space of time as one hour; and it is fair to assume that when such cases are reported they are due to gross negligence, for where the medical practi-

tioner does his duty and calls in to his aid the ordinary means as taught in all the medical schools, of listening at proper intervals and for a sufficient length of time for the heart-beat, he will find that no heart can intermit its beats—that is, remain in perfect repose—for a space of five minutes in time. Cases are cited in newly-born children where 20 minutes have been supposed to elapse after suspension of the heart's action before resuscitation took place, but these are considered as due to imperfect or careless tests.

The respiratory movements coincide generally with the heart's action; all respiration ceasing, this heart never continues to act longer than five minutes, and these movements can be noted by the non-medical observer, by placing a piece of looking-glass, or a dish filled with water or mercury, upon the chest, and allowing the light to be reflected upon the surface; the slightest movement will result in oscillations.

A common mistake of death for a supposititious trance state is the continued or increased warmth of the body, which is so remarkable in some cases; there are instances where days have elapsed before the body was allowed to be put in the ground, because of its continued warmth, and of the absence of the corpse-pallor; and again it has been frequently noted in cases of death from cholera that bodies, which at the time of death were moderately cool, have developed a temperature of 87° Fahr. and of 92° Fahr., and in cases of death from injuries to the nervous system, even a much higher temperature has been reached—evidences, as Taylor puts it, of some latent vital power or chemical force still lingering about the circulating system.

While the trance state is a source of mystery and wonderment to the popular mind, the positive statements of a change of position in a body, and even of the birth of children after death, are something more tangible and real, and carry their convictions in a more decided manner. Yet these phenomena in many cases are accounted for in the most natural way. There is inherent in the muscular tissue of our bodies a certain irritability or tonicity—vitality, perhaps, is a good expression—of the muscle itself, which is independent of the brain, nerves, circulation, or respiration, in that it continues to exhibit its function—that of muscular contraction—for an appreciable time after death has abolished these forces, and physiologists, by supplying the muscles with nutrition, such as the injection of defibrinated blood, have been able to excite this irritability so late as 16 hours after death. It is this irritability which results in the *rigor mortis*, or rigidity of death, and which sets in generally within five or six hours, lasting from 16 to 24 hours. With this rigidity is a muscular contraction usually not resulting in any change of position of the body; but the flexor muscles exhibit a greater tendency to contraction than the extensors, and there are instances where this contraction has been quite marked, resulting of course in a change of position. If a body be not properly laid out and placed in a coffin in the cramped position in which *rigor mortis* has set it, there will necessarily be some change of position when, at the end of the time mentioned, this condition passes off and a relaxation ensues. In one case of death from cholera, half an hour after complete cessation of circulation and respiration, the muscles of the arms underwent spontaneously various motions of contraction and relaxation, continuing for upward of an hour.

SIX CENTURIES OLD, AND UNFINISHED.—There is, in truth, something very noble in that love of art and its highest creations which was for so many years a ruling principle in the Florentine municipality, and is nowhere more strikingly displayed than in the decree by which Arnolfo di Cambio, in 1293, was ordered to undertake the building of their cathedral church of Santa Maria del Fiore. Plans were prepared, but Arnolfo dying in 1300, the same year in which Dante was chosen one of the Priors of the Arts, the work stood still until Giotto was appointed master builder, and assisted by Andrea Pisano, continued the erection of the cathedral according to Arnolfo's design. The building was, however, frequently interrupted, and, in spite of the lofty spirit in which it was commenced, it was only by slow degrees and at long intervals that the cathedral arrived at its present condition. In a few years more we may hope to see finished the facade, and thus we shall be able the better to admire and appreciate Giotto's tower and Brunelleschi's cupola, triumphs of architecture, commensurate with the grandeur of the idea from which they emanated.—*Cor. Geneva Continent*.

THE INDUSTRIAL PROGRESS OF THE UNITED STATES.—The astonishing progress of this country since the war is the subject of remark by the *Baltimore Gazette*, which cites a well-known statistician as authority for the statement that in the 14 years since 1865 the aggregate production of wheat and barley has trebled; corn, cotton and tobacco more than doubled; oats increased nearly 140,000,000 bushels; potatoes nearly doubled, and hay increased nearly one-third. The cotton crop of 1878 and 1879 was the largest ever raised. The ten crops from 1852 to 1861, raised by slave labor, numbered 34,995,440 bales. The ten crops of 1870 to 1879, inclusive, raised by free labor, numbered 41,454,743 bales. In tobacco, also, the South has achieved a gratifying increase in the annual yield. "The possibilities of our agricultural interests," in the language of Mr. Porter, "are as yet an unknown quantity."

Graphite—American Manufacture of Pencils.

[Read Before the California Academy of Sciences by C. D. GIBBS, C. E., Aug. 2, 1880.]

Graphite is a mineral substance of a lead or iron-gray color, a metallic luster, soft to the touch and staining the fingers with a lead-gray hue. It is also called plumbago and black lead; but the latter name is incorrect, as it contains no lead. Its composition is similar to that of anthracite coal, it containing usually 90% to 95% of carbon, with from 4% to 10% of iron, and traces of silica, alumina, lime and magnesia. Graphite is found in crystalline rocks, especially in gneiss, mica slate and granular limestone. Its chief use is for making pencils, crucibles and portable furnaces. It is also employed for diminishing the friction of machinery, and for giving a gloss to the surface of cast iron.

About a century ago the most valuable mine of this mineral, containing the finest quality for making pencils, was at Borrowdale, in Cumberland, England. The entrance of the mine was protected by a strong building, and a guard stationed over it to keep the miners from stealing the mineral. It was only worked six weeks annually, and the net produce of the six weeks amounted to from \$150,000 to \$200,000.

Pencil Manufacture.

The word pencil is used in two senses. It signifies either a small hair brush employed by painters in oil and water colors, or a slender cylinder, of black lead or plumbago, either naked or enclosed in a wooden case, for drawing black lines. The last sort is the one to be considered here.

The best black-lead pencils of England are formed of slender parallelepipeds, cut out by a saw from sound pieces of plumbago, which have been previously calcined in close vessels at a bright red heat. Another method consists in finely pulverizing the graphite, and then by a very heavy pressure, obtained by machinery, condensing it into thin sheets. These sheets are then sawn up of the sizes required. The pencil is pure graphite; and the foliated variety is preferred on account of its being freer from impurities.

The point at which I wish to arrive in this article, is to show that by American ingenuity and the novel features in the application of machinery, one firm is able to turn out so many pencils that it is calculated they produce one-third of the entire number used annually in the U. S.; and are supplanting pencils of the European make. And the pencils are made from graphite, specimens of which are here presented.

The American Pencil Trade.

The pencil works of the Dixon Company are situated in New Jersey, the Graphite mines and mills at Ticonderoga, N. Y., and the Cedar mills at Tampa, Florida.

Graphite of great purity is found at Ticonderoga, N. Y., both in the form suitable for crucibles and for the production of what are erroneously known as "lead pencils." The graphite is reduced in mills to a fine impalpable powder, almost as mobile as water, and making the fingers as smooth as if they had been oiled. Pure clay, or clay containing the smallest proportion of calcareous or silicious matter, is the substance which is employed to give aggregation and solidity, not only to plumbago dust, but to all sorts of colored powders. That earth has the property of diminishing in bulk, and increasing in hardness, in exact proportion to the degree of heat it is exposed to, and hence may be made to give every degree of solidity to pencils and crayons. The clay is prepared by diffusing it in large tubs through clear water, and letting the thin mixture settle for two minutes. The supernatant milky liquor is drawn off by a siphon from near the surface, so that only the finest particles of clay are transferred into the second tub, upon a lower level. The sediment, which falls very slowly in this tub, is extremely soft and plastic. The clear water being run off, the deposit is placed upon a linen filter, and allowed to dry. It is now ready for use.

We now come to

The Third Method of Making Pencils.

The pulverized graphite is calcined at a heat approaching to whiteness. The action of the fire gives it a brilliancy and softness which it would not otherwise possess, and prevents it from being affected by the clay, which it is apt to be in its natural state. The less clay is mixed with the plumbago, and the less the mixture is calcined, the softer are the pencils made of it; the more clay is used, the harder are the pencils. Some pencils are formed of two parts of plumbago and three parts of clay; others of equal parts. This composition admits of indefinite variations, both as to the shade and hardness; advantages not possessed by the native mineral. While the traces may be made as black as those of pure plumbago, they have not that glistening aspect which often impairs the beauty of black-lead drawings.

The materials having been carefully mixed according to the degree of "hardness" desired in the pencils, and the substance having been reduced to a dough form, it is placed in a cylinder, within which a screw works a well-fitting plunger, and at the bottom is the plate having holes of the shape and size of which the "lead" is to be cut. As the coils of tenacious material

issue from these holes, they are cut in lengths equal to three pencils, strained, flattened and baked.

It has been found possible to run a coil four thousand feet long without breaking; such a length of unbroken pencil material having been shown by the Dixon Company at the Philadelphia Centennial Exhibition.

From the mills in Florida the cedar is brought to New Jersey, not in logs, but blocks seven inches long, and these are again cut into strips measuring three and a half inches wide by three-sixteenths thick.

This last fact reveals two differences between the methods usually employed in Europe, for the pencil strip is in this factory made of the width to yield six pencils, instead of being cut single and both halves of the pencil are alike; and not, as in the older method, one portion narrower than the other, both sides are equally grooved; and the process of filling the slips, which is done by hand, is exceedingly interesting. Each girl engaged in filling takes up a grooved slip in one hand and a bunch of the straight "leads" in the other, and with a dexterity begotten of practice, very rapidly inserts six of the stalks in the slip; this being banded to a second girl, and the latter receives from a third worker the second half of the slip, over which a brush of hot glue has passed. The two halves are brought together, each one, it will be remarked, embracing half of the "lead," and then, when a row of these slips has been filled, they are pressed under a screw frame till the glue is dry. The next process is to smooth the ends where the "leads" project; and then we reach another interesting machine. In this machine a revolving cutter seizes the slip and with two cuts removes the superfluous wood, separates the pencils, and rounds them into shape. The pencils fall from this machine in a continuous stream, or rather in six continuous streams, each pencil finished for use, and so smooth, it is said, that the finest sand paper would scratch them.

The chips falling from this machine are sucked away by a blower into the engine room and consumed as fuel, with the result of keeping the place perfectly free from rubbish.

The next curiosity is the counting-board, a grooved board or table, on which by rubbing a handful of pencils over it, and seeing that each groove is full, a gross of pencils can be accurately counted off in five or six seconds. Other ingenious machines are in use for staining and varnishing the pencils, stamping marks and names, and finally packing them in a singular and convenient method—the package being oval in shape. Eighty thousand pencils are made daily; and it is said that by the use of checks on the quantity of material given out, that if even one pencil is abstracted it will be missed.

THE CHRYSOLITE MINE.—The actual condition of this notorious Colorado mine has for months furnished the subject for much direct and random writing on this part of the press and correspondents. The conduct of the engineers who examined and reported upon the property has been condemned severely, if not critically and justly. This state of things has proved an irksome strain upon patience. Accordingly, the *Engineering and Mining Journal*, of which Dr. R. W. Raymond is one of the editors, puts the facts of the Chrysolite's history in a nutshell. That journal says: So far as the probable truth can be eliminated from the mass of sensational and stock-jobbing rumors, it appears to be that, in the absence of Superintendent Keyes, the work of development of the mine and the preparation of stopes had not been pushed with sufficient energy to secure the maintenance of a large output; that the daily product of the mine has, in consequence, fallen off greatly; but that the grade of the ore remains good; that the direct and indirect effects of the strike and of the diminished output have altered for the worse to some extent the financial situation of the company, as prophesied in Dr. Raymond's letter from Leadville last May. In other words, although the company, from all that we can learn, has reduced its indebtedness of that date, it has not reduced it as much as was then expected. It is very likely that several months may elapse before the payment of dividends can be resumed, if the policy of paying debts before paying dividends is to be adopted and adhered to. There is nothing in all this to warrant the stories that have been circulated against the value of the mine, and we are sorry that the people who are making fortunes out of the panic they have themselves created should have been able to use the *Mining News* for that purpose.

STRIKE IN A NEVADA MINE.—The *Eureka Sentinel* of the 6th inst., learns that an important strike has been made in the William mine, in Prospect mountain. About one week since a horizontal cave was encountered in a drift on the 360 level. Good ore at once came in, and the body has been steadily improving to the present date. The ore body has been represented to the *Sentinel* as being about eight ft. in width. Its dimensions in other directions have not yet been determined. The discovery was made at the lowest point reached in the mine. The fact that the ore carries a larger per cent. of lead (47) than usual, leads the fortunate owners to believe that they have made a development unequalled on the mountain for its value and permanency. The Williams has always been a first-class mine, yielding ores immensely rich in gold. Now that a great bonanza has been discovered there is no estimating the value of the property.

Mechanical Progress.

The truth of the old proverb, "Necessity is the mother of invention," can no where be better demonstrated than in California. The pursuit of industries under the peculiar conditions which prevail in this new world has brought to light a host of needs, and these needs have spurred painstaking and ingenious inventors to their best achievements. The result is, we can point with pride to the many mechanical triumphs which have been won in the city workshops, at the country forge, in the miner's cabin, and by the farmer's fireside. It can be truly claimed, we believe, that in no part of the country have there been brought forward so many useful inventions, in proportion to the population, as in California; or, in other words, no where else in the United States have so few people found so many new and successful ways and means of attaining desired ends. This is one of the most interesting features of our grand industrial progress, and at the same time one secret of it. We have vast and rich natural resources, it is true, but it is the skill of the inventor, and the enterprise of the men who have used his materials and methods, which have developed these resources and given us a prosperous State.

It is not within the limits of our space at this time to enumerate the individual achievements which have ministered to our industrial advancement. Indeed a volume might be written upon the subject without exhausting it. We can only allude in a general way to the point proposed, trusting to our well-informed readers to trace the steps by which our distinctive position has been attained. Our oldest industry, mining, has been developed from the crude practices and implements of the argonauts into systems of mechanism and processes which are far in advance of those employed in mining operations elsewhere. Our foundries have in their pattern-room shapes and forms of material which, to the skilled eye, convey ideas of amounts and speed of accomplishment greater than any other mechanical engineers have attempted. Our chemists and metallurgists can show methods and appliances which cannot be illustrated anywhere else in the world. The 30 years of active mining on this coast has done more for the development of mining art than have centuries in the older mining countries. Nor have the achievements in the mines themselves been less significant than in the machine-shops and the laboratories. Old methods of working mines proved as inadequate as the old tools and machinery, and the practical miner joining hands with the inventor, the machinist and the scientific student of materials, has forced the mining industry of this coast into a position which, for originality and adaptation of means to ends, is in many respects unequalled. The result is that the experts of all nations come to us to learn methods and mechanism, and their reports well define our standing.

In agriculture, which is now the leading industry of our State, there has been a line of mechanical progress as clearly marked and as beneficial in results as in mining arts. Our farmers grappled with conditions so novel that their experience elsewhere was but of little avail. In fact the earlier years of California farming was in many respects marked by the failure of what seemed feasible, and this was followed by the success of what seemed impossible. Here, too, is material for a volume, and we cannot enter upon it. Suffice it to say that the throwing down of old practices and the gradual development of new called for an almost entirely new fashion of mechanical devices, and this has been brought into existence by the patient labors of our inventors and manufacturers. In amount and cheapness of work accomplished the agricultural machinery of California is altogether without a rival in the world.

Bearing in mind these two grand lines of mechanical progress developed in our State, it is little wonder that an institution with the honorable aims and practical value of the Mechanics' Institute has grown and flourished in San Francisco, which is the center of our industrial system. It is little wonder that the fairs which have been held have been regarded as the occasions for bringing to public notice the triumphs which skillful workers have secured. We expect that the fair which is now beginning will take its proper place in the series of exhibitions, and will be an exponent of our signal advancement in industrial arts, showing to all the progress which each individual worker has secured, and giving to all an opportunity for study and contemplation of our natural resources and the means for developing them in the interest of mankind.

A NEW NICKEL ALLOY.—Alumi is the name given to a new alloy of nickel and aluminum, for the composition of which the United States letters patent have lately been granted. It is intended to be used in place of nickel anodes in electroplating. It is said to deposit, under the influence of the electrical current, a white, smooth surface, susceptible of taking a high polish, and giving a soft, silvery appearance.

PETROLEUM is now used for the illumination of all except three of the lighthouses of the coast of France.

USEFUL INFORMATION.

THE NORTH POLE.—The most vigorous efforts to reach the North Pole, or to make any near advance to it by means of direct approach from any one given point, having all proved failures, a new plan of action has been suggested—that of reaching it much after the plan of a military investment. It is now proposed to establish a circle of permanent observing stations around the northern polar region. In the furtherance of this proposition, the Danish government has resolved to establish a station in West Greenland; the Russian government will establish two, one at the mouth of the Lena, and another on the new Siberian islands. The U. S. has resolved to plant an observatory at Point Barrow in Alaska, and it is expected that Canada will occupy some central point on her Arctic frontier. Holland has provided funds for a station in Spitzbergen, and Norway will select some point in the northern extremity of Finmark. In addition to these national undertakings, Count Wilczek will place a corps of observers upon Nova Zembla. The line of this circumvallation, by posts of observation, will not be far from 4,000 miles in extent, along which the observers will be placed at an average of only about 500 miles distance from each other. It is possible that this may lead to some plan of advancing posts, and keeping them up within supporting distances upon some more or less direct line. In this way, it is thought, the Pole may be eventually reached, and the circumpolar regions explored and mapped in aid of science, if not for the advancement of commercial interests.—*Californian*.

NEW VARIETIES OF TEA.—An English consul reports the discovery of two curious varieties of tea on the western frontier of China. In the monasteries on Mount Omi (or Ngomi) he was given an infusion of tea which is naturally sweet, tasting like coarse congo with a plentiful addition of brown sugar. It is only grown by the monks on the slopes of the mountain, and two days' further west its existence was unknown. The other variety, odd as it may appear, has the natural flavor of milk, or, perhaps, more exactly of butter. What is most interesting is the fact that it is wild tea, growing in its native elevated habitat without cultivation. This wild tea is found in the uninhabited wilderness west of Kiating and south of Yachow, at heights of 6,000 ft. and upward, and is a leafy shrub 15 ft. high, with a stem 4 inches thick. Every part of the plant, except the root, is used for making the infusion; the wood is chopped up and put into a kettle of water with the dried leaves and twigs, and being boiled yields a strongly colored but weak tea, possessing a buttery flavor, which gives it some resemblance to the Thibetan preparation.

DRY FOG.—It has been frequently noticed that during fogs near large towns the air is not saturated with moisture, the dew point in one instance being as much as 10° C. below the temperature of the air. Seeing the possible connection between this phenomenon and the fact that the evaporation of water is greatly retarded by its surface being covered with a film of coal tar, the author made a series of experiments on the comparative rates of evaporation of water, when freely exposed to a current of air, and when covered with a film of coal tar or of coal smoke. It was found that the film retarded the evaporation from 92.7% to 66.6%. The results of these experiments point out a condition of very common occurrence, competent to produce "dry fog," while they also explain the frequency, persistency and irritating character of the fogs which afflict our large towns.—*E. Frankland, Proc. Roy. Soc.*

EMERY PAPER is frequently found lacking in retaining equal efficiency, the fresh parts hitting too much, and the paper soon getting worn through in many places. Emery has been tried on linen, but with little success. A paper or board has been recommended in which emery enters as a constituent part. It is advised to employ fine and uniform cardboard pulp, with from one-third to one-half its weight of emery powder thoroughly mixed with it, so that the emery may be equally distributed. The mass should be poured out into cakes of from one to ten inches in thickness. They must not be pressed hard. Such a paper, it is said, will adapt itself to the form of the articles, and will serve until completely worn out.

GLYCERINE AS AN ILLUMINANT.—Pure glycerine, it is said, may be burned in lamps, provided the wick is so arranged that it shall not be elevated above the surface of the liquid, as the viscosity of the substance will not permit of its being fed upwards by capillary attraction. The flame of glycerine, like that of alcohol, is almost colorless. Glycerine, however, is easily mixable with a variety of substances that will impart luminosity to the flame, and a number of substances rich in carbon may be added to it for that purpose. It is not improbable that circumstances might arise where these facts would be useful.

TO DETECT STARCH IN SUGAR.—It is said sugar adulterated with starch may be detected by a very simple test. A little pure sugar is taken in the mouth and when dissolved is replaced by a little of the suspected article. If the latter contains starch, glucose or chloride of tin, a distinctly bitter taste will be present.

TO BLUE GUN LOCKS.—Gun locks and revolver barrels, being usually made of steel, are rendered blue by simply being subjected to heat. The articles are first finely polished and then subjected to a uniform heat, gradually applied. This is best done by immersing them in hot ashes or sand, and carefully watching the effect of the heat. As soon as they acquire the right color, they are to be taken out of the sand bath and plunged in oil. The temperature necessary to obtain the color is from 500° to 600° Fahr., the last giving the darkest shade.

TO WHITEN RED NOSES.—Meryl is the name of a secret preparation to bleach red noses. It has been examined, and found to consist of a liquid containing benzoic acid, salicylic acid, and thymol, and a powder composed of oxide of zinc, French chalk, and a trace of carbolic acid. It is evident that the discoverer of meryl thinks the red color of the nose to be due to a beginning of decomposition, since all the aromatic antiseptics enter into the preparation of his nostrum.—*Journal of Chemistry*.

COMPOSITE DIAMONDS.—A diamond expert of Chicago asserts that many of the so-called solitaires, sold as single stones, are made up of small stones cleverly put together. Under the blowpipe they separate. He adds the surprising statement that not one diamond in ten sold in this country is other than the refuse of the London market. Nearly all are off-colored, speckled or feathered, and are sold at a fictitious value.

ROOF VARNISH.—A varnish for roofs has been recently patented in Germany which is composed of 35 parts of clay slate, 30 parts mica slate and 35 parts resin, all finely powdered and heated with 50 parts of tar.—*Boy, Ind. und Gewerbeblatt*.

A NOVEL INDUSTRY.—From saw-dust, ground-up twigs and like materials, pails, tubs, molding for buildings, doors, sashes, blinds, etc., are now manufactured at Great Falls, Windham, Maine.

It is said that some of the sarcophagi of ancient Egypt bear the marks of having been hollowed out with tools of the crown or cylinder-saw order.

GOOD HEALTH.

Dr. Tanner's Fasting Experiment.

Its Lessons and Philosophy.

Of all the exhibitions which have attracted the attention of the people in and around New York City, the forty days' fast of Dr. Tanner is not the least remarkable. If his aim was to draw public attention and be extensively noticed, he has fully attained it, as no daily paper can be taken up which does not contain a full account of his doings and feelings of the last 24 hours, while he is watched by the physicians of the allopathic as well as of the eclectic school, and in addition to this always by a *Herald* reporter, to make sure that there is no deception practiced, as has been so frequently the case with other pretended fasters.

That his experiment is not altogether useless, as is maintained by some, we will try to elucidate, notwithstanding we agree that the sacrifice and danger he exposes himself to appears so great that it is doubtful if they will be compensated for by the physiological and pathological lessons to be learned by it.

His fast has, in the first place, proved the mistake of those who judged all men alike, and reasoned that because a weak, hysterical and ill-fated girl of 18, perhaps consumptive besides, died within two weeks from starvation, as soon as she was carefully watched, therefore nobody could be without food for a period of 40 days, forgetting that the case is quite different where we have a man of between 40 and 50, the age of maximum resistance, a man well fed, of whom the weight is far above the average for his size, and who was provided with a copious layer of adipose tissue around his body, a man who had practiced fasting for sanitary purposes, finding it the best way for him to cure gastric derangements, for which he had a liability, and who had gradually increased the time of fasting until, at his last fast in Minneapolis, he had extended it to 42 days. This was not believed and deception suspected, hence a challenge for \$1,000 if he succeeded when carefully watched. Dr. Tanner accepted, but the challenger backed out under some pretext, and Dr. Tanner, to save his reputation and prove his theory, came on and submits for nothing to the task under the eye of careful watchers.

It must be conceded that few persons would possess such a strong will and determination to persist in subduing all appetite, and disregard the no doubt exceedingly disagreeable and perhaps distressing feelings consequent to total abstinence from food; but Dr. Tanner possesses this determination in the highest degree, and he never thought of cutting the fast short, whatever may sometimes have been the opinion of his watchers.

In order to understand what may be learned from this experiment we will, for the benefit of the non-professional reader, remind him of a few physiological principles.

The chemical constituents of the human body have to be constantly renewed, and the waste has to be supplied by the food. Some of these constituents are wasted rapidly, others slowly,

and in case of starvation the elements rapidly waisting away must be present in the body in sufficient quantity to keep the functions of life in operation. These rapidly wasting constituents may be divided in three classes, those in which carbon prevails, those in which nitrogen, and those in which phosphorus is the prevailing element.

The carbonaceous compounds are wasted in keeping up the animal heat. This is accomplished by a slow combustion, that is, a combination of the carbon with the atmospheric oxygen, which is continually going on in the capillaries through the whole body, the oxygen being furnished by the blood, which absorbs it in the lungs, and which by the arteries is sent through the body. The product of this combustion, the carbonic acid, still absorbed in the blood, is by the veins sent to the lungs, where it is given off and escapes in the act of respiration. After having stripped Dr. Tanner, when he commenced his fast, for the double purpose of ascertaining his physical condition and leave no doubt that he had no food about him, it was seen that he had plenty of fat in and around his body to furnish carbon enough to last him more than forty days.

The second element of rapid consumption is nitrogen; it proceeds from the waste of the muscular tissue, which is always going on, even during sleep, as the heart is a muscle continually contracting, and respiration is kept up by muscular action. The blood takes up this waste in the form of a compound, of which the chemical name is cyanate of ammonia, but which by physiologists is called urea. It is the function of the kidneys to secrete this from the blood, and numerous experiments have settled the nature and amount of this secretion, which in healthy persons consuming food varies from 25 to 35 grams every 24 hours. When Dr. Tanner began his fast it was secreted at the rate of 29 grams, and as the nitrogen in any excess of nutrition is similarly changed and secreted, it was expected that a large reduction would be observed as soon as the fast began to have effect on the system. This expectation was realized, and the amount soon fell off to 23, 20, 17, 16, and finally 13 grams, at which it remained stationary, with slight oscillations beyond. This amount of nitrogenous substance represents, therefore, the waste necessary to sustain the functions of life, and would at once be increased in case food was taken by the experimenter, at least nitrogenized food, such as beef extract or its equivalent, albumen, casein, milk, etc., the only substance which would be of benefit to him. Analytical chemistry, therefore, acts here as a reliable detective, and to the credit of all concerned it must be said that never the least suspicious increase of urea was observed, it remaining very nearly constant, and will no doubt become double and more as soon as after the fast food is again taken.

The third element of rapid waste is the phosphorus; it proceeds chiefly from the waste of the brain and nervous tissues. It is so important in these functions that a great German chemist has formulated the expression, "without phosphorus, no thought." Every mental act and every nervous excitement is accomplished by a consumption of phosphorus, which, combined with different bases in the body, especially soda, magnesia and lime, is secreted by the kidneys as a soluble salt, not only easily detected as crystals by the microscope in the sediment, but even an approximate estimate may be had of its reduction or increase by the number of crystals seen in the field under the same circumstances.

This third element did not at first show any reduction in quantity, but, to the contrary, for a few days some increase. It was at the occasion that Dr. Tanner had been unjustly accused by a physician present that he had surreptitiously accepted food from one of the watchers; this appears to have preyed upon his mind. Attention was therefore called to the danger in this direction, a danger proceeding from the more rapid waste of the nervous system. Relaxation was therefore devised, and daily carriage rides, which eased his mind and were followed by a more sound sleep, soon reduced the phosphates secreted, and at the same time reduced the irritability and temper of the experimenter.

This observation tallies perfectly with what has been observed in the case of such clergymen who have every week the periodical labor of preparing and delivering two sermons on Sunday. Chemical analysis has proved that at that time they secrete more phosphates than in the middle part of the week, after the rest of Monday and Tuesday.

We will only add that the suspicions occasionally expressed by those who cannot realize the possibility of so long a fast are utterly unfounded. All those who have taken the trouble to watch long enough, especially if they became acquainted with Dr. Tanner, came to the conviction that he is too high-minded, upright and honest to deceive any one with so mean a device as to take food secretly; while in regard to the responsibility of the watchers, it must be considered that Dr. Tanner can any time obtain what he wants. If he asked, for instance, for a beef-steak it would be procured at once, but this of course would end the watch, being the close of the experiment.

He told us that some years ago he was married, but became disgusted with his wife, who, he says, continually stuffed her stomach with all kinds of food. He could not stand this, and when remonstrance did not improve her he obtained a divorce.—*Scientific American*.

The Week.

Since our last issue news has been received from the Government yacht *Freda*, which was dispatched to Socorro island, in the hope of finding and rescuing the ill-fated captain and party of the *Mathilde*. Capt. Yates has written from Mazatlan that he had discovered no traces of the missing boat's crew, after a thorough search. As we write the news comes to us of the return to this port of the *Lancashire Witch*, with the report that she also failed to discover the missing boat of the *Mathilde*.

The Industrial exhibition continues to be the pleasant and interesting feature of the city. Since the various exhibits have been placed in form, the interest of the public in town and country has greatly increased, and the daily concourse is large and gratifying to both the exhibitors and the managers. For the especial benefit of our readers in the country, we think it worth while to mention thus far in advance of the time, that arrangements have been made for a visit to the fair by President Hayes and General Sherman and party on the afternoon of the 8th of September. It is safe to predict that there will be an immense throng on the occasion.

Advices from Europe received in this city on the 25th inst. represents the home supply of wheat in both England and France as larger than it has been for a number of years, and further, that the demand for American wheat will be less than it was last year. As our wheat crop is enormous, the market for the heavy surplus will probably not be as brisk as usual. Well, full granaries nerve one to face the vicissitudes of a year.

We get the most satisfactory news from the mining regions of the State. It is the beginning of the cleaning-up season at the placer and gravel claims; several companies have already done so with fine results; and the finish of the business will show a large product of gold. On the Comstock, just now, the most interesting operations are progressing in the mines at the north end of the great vein; the results of which may put several of them in bonanza. The prospect is highly encouraging.

Color-Blindness.

The knowledge of color-blindness has become developed to the extent that it enters into the practical business of life; for in one State (Connecticut), at least, it governs the retention and choice of the men employed on the railroads. Lately, William Pole, an English amateur in science, and himself a victim of color-blindness, has written a paper on the subject, which embraces all that is known about it. He shows just what the color-blind see. The affection is confined almost exclusively to men, although instances of it have been known in women. It is estimated that about 1 in every 25 men is defective in color perception. The peculiarity is assumed to be hereditary and of great antiquity, although it is only within a century that it has been definitely described.

A poor English shoemaker, named Harris, was the first to notice the defect in himself and to suspect its existence in others. His case was the subject of a paper read before the Royal Society in 1757. It was reserved, however, for the distinguished English chemist, John Dalton—author of the "New System of Chemical Philosophy," in the first volume of which he explained his atomic theory—to elaborate and generalize the facts of color-blindness. Dalton was nearly 30 years of age before he noticed his defective vision, for one day while comparing his impression of the color of a flower with that of his friends, he became convinced of his visual peculiarity, and was led into its investigation. The result was the first distinct setting forth of the difference between the color-blind and people of normal sight. Sir John Herschel, who became interested in Dalton's case, set him to matching various tinted skeins of silk, the result of which clearly revealed that the color-sense was lacking.

Mr. Pole was also, like Dalton, about 30 years old before he was conscious of his defective vision, and his investigations show that color-blindness presents similar general characteristics in all its subjects. He says that, "strictly speaking, Daltonism (the name sometimes given to color-blindness) has only two color impressions—yellow and blue; yet the sensations of one color-blind give him, 1, pure white; 2, pure black; 3, infinite varieties of gray; 4, yellow in a great variety of intensities; 5, combinations of these with the varieties of gray; 6, blue in a variety of intensities; and 7, combinations of these with the varieties of gray." Such color sensations as red, green, orange, violet and all their combinations are unknown to the color-blind. Still, these colors make upon him distinct impressions. Red, for instance, appears dark yellow or yellow brown; pink or crimson seems simply gray or a dark blue. Green is more perplexing: yellowgreens, such as predominate in nature, appear as a combination of gray and yellow; neutral greens, varieties of gray; and blue greens, combinations of blue and gray. Violet appears a dark or shaded blue, and brown a mingling of yellow or gray. Mr. Pole is convinced that genuine color-blindness is past remedy. It is a constitutional defect, and is generally hereditary. There are still conflicting theories respecting this visual defect, and it is an open subject of investigation.

Considering the disadvantages of the color-blind in following many pursuits, Mr. Pole says it is remarkable how well they have got along. Dalton became famous in chemistry, a science in which color is one of the important elements of observation; and Mr. Pole himself succeeded as a draughtsman and colorist of drawings. His remarks on color-blindness in those employed on railroads are highly interesting. He says:

"Most people know that red and green lamps are used at railway junctions, the former to stop a train, the latter to allow it to pass on; and at sea the use of red and green lights on the two sides of a vessel indicates to other ships the way she is going, in order to avoid collisions. Now, as one of the most common symptoms of color-blindness is the confounding, under certain circumstances, of red with green, it is taken for granted that a color-blind engine-driver or helmsman must be unable to distinguish between the contradictory signals, and frightful pictures are drawn of the danger that the public are constantly incurring. But what says the inexorable logic of facts? In this country we have not only had a tolerable experience of the working of railways for half a century, but we have gathered a mass of information about railway accidents which is unknown elsewhere. Every casualty that occurs in the three kingdoms is carefully inquired into by a government board, and a report is published as to its causes; and yet, so far as I know, never, in a single instance, since railways have been in use, has an accident been traced to the mistaking of a red for a green night signal. And when we consider that, according to the statistics, about one in every 25 engine-drivers must have been color-blind, it follows that, if the notions of the alarmists had been true, numbers of collisions would have occurred every day—in fact, that the traffic of the country could not have gone on. The truth is, the agitation has arisen from the difficulty the normal-eyed investigators have in understanding exactly what we, the color-blind, really see. We could tell them that although the red and green lights do not give us

the true red and green sensations, yet still they are strongly contrasted to us, and we are in no danger of mistaking one for the other. On the whole, then, I think the alarm on this subject is unnecessarily magnified; but at the same time I do not deny a possibility of danger under certain circumstances, and I would by no means discourage reasonable precautions in the selection of men."

Chromic Iron.

The following letter from the State Mineralogist, answering certain inquiries of the County Surveyor of San Luis Obispo, we copy from the *Tribune*:

CAL. STATE MINING BUREAU,
Office of State Mineralogist,
San Francisco, Aug. 7, 1880.

MR. EZRA CARPENTER—Dear Sir: In your letter of July 13th, you ask for information as to the cost of erecting works for the reduction of chromic iron. The treatment of chromic iron is briefly as follows:

First, the ore is very finely pulverized, sifted, or holed, and placed on a reverberatory furnace with salts of potash and the heat continued until the chromic ore is decomposed, and the chromic acid combines with the alkali forming crude bichromate of potash. This is raked from the furnace on a brick floor, and when cold is leached with water in a suitable tank, which extracts the soluble bichromate of potash and from which all the chrome products are obtained.

You will see that its manufacture depends on a supply of potash which cannot be obtained on this coast and must be imported. This would probably be fatal to its manufacture here. Other alkalies, such as soda or lime, might be substituted for the potash, but the only gain in that case would be the concentration, as it would nearly all have to seek a market elsewhere.

It is my opinion that if the manufacture of chromic products should be undertaken, the first works should be small and experimental, otherwise great loss of money would result, even should success eventually follow.

Chromic oxide is largely used by the Government in printing greenbacks. This might be manufactured to advantage, as might also be the chrome yellow and the chrome green used on the Pacific coast for paints. But any manufacture should be undertaken with the understanding that the market is limited.

Chromic iron is also used in the manufacture of a hard alloy with iron, which for some purposes takes the place of steel. For this purpose it could not be at present utilized here.

Very truly, etc.,
HENRY G. HANKS,
State Mineralogist.

SOLID SILVER IN NEW MEXICO.—A correspondent of the *Denver Tribune*, writing from Silver City, Grant county, N. M., gives this slight sketch of a successful miner's history. It has all the charm of a romance. About 12 years ago, says the writer, W. Breemen, the newly-elected Mayor of Silver City, came to Grant county with a small sawmill. There was no Silver City then, not even silver. He sawed the first lumber for the town, and afterwards commenced to mine, and to-day he has an extensive mill in full tide of operation. He is the owner of the "76" and "Breemen," in Chloride Flats, one and one-half miles distant from his mill. In his office I found the finest cabinet in the Territory, by all odds. In fact the mineral contained therein is worth more dollars than any dump in New Mexico. I confess that I was surprised on examining the rich silver specimens contained therein. I saw silver that is just as near pure as a mine can turn out. I was taken to a room where at least 10 tons were stacked, all of the same being so pure that a stamp mill would fail to crush it. At his mines he has plenty of the same sort. Recently a blast at "76" developed a chimney that his foreman knows not the depth of, and I was told that silver almost pure showed itself in increased quantities. Those who know say there are \$1,000,000 in sight. He has had offers repeatedly for the mine, but he does not want to sell. He is merely taking out enough ore each day to supply his mill in the city.

BLACK DIAMOND COAL MINE.—This property appears to be in fine and prosperous condition. The works at Nortonville were visited recently by the editor of the *Antioch Ledger*, who furnishes some interesting details of the company's operations. He says: The apparatus at the mines is in a high state of perfection. During our visit, between the hours of 1 and 4 o'clock P. M., on Saturday last, there were hoisted from the main shaft 212 cars of coal, containing each one ton, besides 200 men and boys and twelve horses, the men and horses, as we were informed, being equal to about 32 cars of coal. Mr. Morgan informed us that between 500 and 600 tons of coal would be taken out of the mine that day, for which a ready market is found, as was shown by the bunkers, which were, at the time of our visit, nearly empty. Some 8 or 10 boys and men were engaged in screening, and nothing but pure coal was allowed to pass into the bunkers. Probably there is no coal mine on the coast which has such extensive machinery and complete arrangements for work. To those who have never examined anything of the kind, it is well worth a trip to Nortonville.

Lixiviation of Gold and Silver.

The following extract from a coming work on this subject, by Charles H. Aaron, will be of interest. Speaking of the point at which the leaching of the chloridized gold begins, the author says: At this point arises a difficulty from the fact that a large quantity of chlorine remains in the vat, the escape of which into the leaching room is not desirable. If the cover of the vat be raised the gas is visible like a green ssa above the ore; a pestilential ssa whose waves, surging forth upon the slightest disturbance of the air, threaten to envelop and suffocate the workman, unless he hold his breath while boistering the cover and fastening the tackle, and then retreat in haste till the storm is over; and even then the same troubles recur while water enters and displaces the chlorine still remaining beneath the filter and permeating the loose mass of damp ore.

To overcome this difficulty some operators fill the vat with water before lifting the cover, and, by means of a rubber hose, convey the expelled gas either out of doors or into another vat charged with ore. There are two objections to this plan—firstly, a great deal of chlorine is absorbed by the water which has an unfavorable effect in the precipitation of gold, making it more difficult to settle, as well as wasting the precipitant; and, secondly, the water entering the tub in one large stream descends through the bed of ore at one point, and rises through it in other parts, a solution of nearly uniform strength throughout the mass, and requiring a large quantity of water to complete the leaching, taking more time and giving finally a weaker solution than is necessary for the precipitation, which takes place better when the solution is strong.

The proper way to apply the water is by spraying it all over the surface of the ore in the vat so that, percolating downward through the mass, it carries the greater part of the gold chloride in the first portion of the water, and a rich solution is got at once, while less water is required to remove the whole of the gold, and the stronger solution thus finally obtained gives a better precipitation on addition of iron sulphate.

But if the spraying is undertaken by hand with a sprinkler, the loose ore, settling as it becomes wet, expels chlorine in such volumes as render it impossible for a man to stand near the vat.

The course I adopted was to place a coil of lead or rubber pipe, perforated by many small holes, around the vat under the cover. After raising the cover the water supply pipe was connected with the perforated coil, and the water, under moderate pressure, issued in a number of fine jets, and showered all over the ore, through which it descended gradually, dissolving the gold chloride as it passed, so that the first solution that passed through the filter and filled the space under it was very rich, while that which finally remained on the top was very weak. The discharge was then started, and the water thenceforth admitted in the usual way, keeping the surface of the ore covered until the leaching was finished.

This plan, however, is still open to the objection that it gives a solution containing much free chlorine, while the chlorine which is expelled is not removed from the room, whence it is very desirable that means should be used to abstract the surplus from the vat before raising the cover or admitting water; and the appliance I am about to describe will not only do this, but will also save the chlorine for use in another charge of ore with little waste.

Before lifting the cover, the plug-hole being open, one of the lower openings, either the nipple through which the gas was admitted or the discharge pipe, is connected by a rubber hose with the interior of an inverted bell of sufficient size, which is immersed in a tank of water, precisely like the "gasometer" of gasworks, and like it, counterpoised and suspended by rope or chains passing over rollers, so as to allow the bell to rise or fall in its water tank.

By adding to the counterpoise weights, the bell is gradually raised, and the chlorine is withdrawn from the vat and enters the bell, while air entering the vat through the open plug-hole in the cover replaces the abstracted chlorine. The filling of the vat with water is then proceeded with in any way that may be convenient, without annoyance from escaping chlorine.

The chlorine in the bell may be again expelled when wanted, and caused to enter the same or another vat, by simply removing a part of the counterpoise and allowing the bell to descend by its own weight.

A SUGGESTIVE POCKET.—The late find by a miner, while making his final clean-up below Indian flat, of a pocket of nuggets valued at \$1,300, suggests to the Nevada City *Transcript* the inquiry, where did they come from? The nuggets, weighing from six ounces down to half a pennyweight, were found to have been at one time under a very heavy pressure, as though placed between two rocks and mashed flat. It has been suggested that probably there is an ancient channel in the bill above the claims, and it is altogether probable that a company will be formed, and a tunnel run for the purpose of testing the theory advanced.

The Women and Silk Culture.

From east to west the women seem to have laid bold upon the problem of silk culture with a vigor and earnestness which cannot fail. There is something eminently proper in women assuming charge of the production of silk, and when home-made silk dresses appear upon our streets, the wailers of the good old times of the spinning wheel and home-spun will be silenced. It might be a fine thing for the wife of the President of the United States, to offer a prize for the first silk dress produced from worm to flounce by the wearer thereof.

They have in Oakland a Woman's Social Science Association, one of the favorite themes of which is silk culture. A year or more ago the subject was under consideration, and last week it was attacked again and much interest elicited. It seems that woman was the pioneer in silk growing, for the essayist at the Oakland meeting, Mrs. J. H. Smyth, cited the fact. A woman, an empress, actuated by the noblest sentiment—love for her husband and his subjects—was the first to discover and utilize the labors of the silkworm. The Emperor Hoang-ti, who lived 2,600 B. C., was desirous that his legitimate wife, Si-ling-chi, should contribute to the happiness and prosperity of his people; therefore he charged her to study the habits of the silkworm and to try to utilize its threads. Animated by the noblest impulses, she caused great quantities of them to be collected together, in order to make herself familiar with every detail while feeding and tending them. By so doing she not only discovered the means of successfully rearing the larvæ, but still further, the manner of winding the silk from the cocoons, and of employing it in the manufacture of fabrics. It is through gratitude for so great a benefit, says the historian, that posterity has deified this noble woman and rendered her particular honors under the name of the Goddess of Silkworms. Up to the time of this empress the Chinese clothed themselves with the skins of animals, but after her great discovery they applied themselves to the manufacture of cloth. The Oakland ladies propose to emulate this illustrious example, and continue the discussion of silk culture until some practical results ensue. At an early date an essay will be read by Mrs. T. H. Hittell, of this city, who is an earnest advocate of the introduction of the industry as a household labor.

Inasmuch as the subject is being thus promoted in this State, we propose to state what other ladies are doing in the same direction in Philadelphia. Some time ago we alluded to the formation of "Women's Silk Culture Association" in that city. We have just received the reports of the first season's work of the society, from which we take leading items. The managers give assurance that they have tested the practicability of raising the silk worm within the city of Philadelphia, have found the task fully as difficult as was expected, and have attained results quite equal to their anticipations. They have located a great many mulberry trees around the western parts of the city, and have found what their yield in leaves is likely to be in the future, also, what the expense in time and money required to bring them to the society. They have raised the cocoons, the moths and the eggs in efficient abundance to proceed to the next step—the reeling—whenever a reel sufficiently light, cheap and easy-working shall be obtained. They have instructed a class of scholars in the art of raising the silk worms. These have been taught through the instrumentality of notes dictated by the superintendent and taken down by each scholar. They have developed a widely-extended interest in the culture of silk, and have gathered up and concentrated the products of widely-separated districts of the country. They have cocoons from Alabama and Florida, and splendid specimens, produced by careful feeding, in Delaware; also from New Jersey and Pennsylvania. A lady, stimulated by the example set last year, has raised a large crop at Chadd's Ford, and another has just produced a quantity of fine cocoons at the Permanent Exhibition Building. A lady of fortune, at Kennett's Square, has raised a large number also, and individuals all around, at Holmesburg, Bridesburg, West Philadelphia, in Bucks county have been in-

cited by this "women's" movement to try a hand at silk raising. They have sold silk worms and eggs to parties all around the city. The farmers are beginning to interest themselves about it, and are utilizing their spare beds and their wild mulberries as never before. They begin to see that mulberry leaves may become a marketable article, and that their boys and girls may use their idle time and talents with benefit to all. It is the expectation of the society that the country people will establish similar schools of instruction in many parts of Pennsylvania, under the same charter which provides for "branches" everywhere. Perhaps the silk reformers of Oakland may ere long undertake a practical promotion of the subject after the Philadelphia style.

ENGLISH AND AMERICAN RAILROADS.—The contrast between the British and American system of railroads is very remarkable. The mileage of the former is only 17,696 miles, the latter 86,497. The cost of the former is \$3,585,000,000, double our funded national debt and close upon the total of the English debt. The cost of our system in operation to December 31, 1879, is placed by Mr. Poor at \$4,416,000,000 on 84,232 miles, or \$4,919,000,000 on the whole system of 86,497 miles. The difference in the average cost per mile is very great—in Great Britain, \$202,000 per mile; in the United States, \$50,000 average per mile. The gross earnings, on the other hand, are directly reversed. The British lines, on 17,696 miles, last year took in \$308,000,000. The lines of the United States, on 84,232 in full operation last year, took in \$529,000,000. The propor-

Too MANY IRONS IN THE FIRE.—A certain facile and flighty inventor got this quaint notice from the Rochester (N. Y.) Herald: Edison begins to think about a flying machine. He will soon have one, no doubt, almost completed, lacking only the finishing touches for complete success at his wonderful laboratory in Menlo Park. All he is waiting for now is the suggestion which will ensure success. Edison's collection of unfinished machines and devices is a large one. There is the phonograph, the electric light, the electric engine, and soon we shall have the flying machine. In the meantime he may perhaps some day come across a quaint scriptural passage which reads as follows: "Ephraim is a cask not turned." Perhaps that will suggest something.

AN ÆSTHETIC DEVOTE.—This portrait of an æsthetic devotee is drawn by London Truth: Her dress is semi-Greek. Her hair is fillet-bound in front, and falls on her neck like a little wisp of hay. Her chin is well in the air, and her haggard eyes are fixed on a vase of lilies. Her arms are quite the longest, and almost the thinnest, I have ever seen, but she makes great play with them in expressing her woeful thoughts. As I watch her with deep and pure enjoyment I recall a short simple anecdote of the lady which was told me not long since. She was walking in her garden with one she deemed a kindred spirit. The lunch bell rang. The kindred spirit, after a few minutes' delay, and aware that lunch outlets are better hot than cold, ventured to suggest a move to the dining-room. The lady said, with one of her sweetest,

The Forest Area of the United States.

As we have heretofore noted, the subject of our forest wealth and the influences affecting it will occupy one of the series of valuable reports upon industrial topics which will accompany the volumes of the census of 1880. The investigators are now upon this coast making a thorough study of trees and of forests. The census of 1870 disclosed some very interesting facts concerning our forest area, but that of 1880 will be expected to be much more comprehensive, definite in detail and accurate than the last attempt made by the enumerators. It will be some time before the results of the new examination can be set forth; but as interest has generally been awakened by the appearance, here and there, of Prof. Sargent and his colleagues, we recur to the deductions from the last census as likely to give information which will be of value to those who now find themselves drawn to a consideration of our forest areas.

The report of the United States Department of Agriculture for 1875 contains some valuable deductions made from the census of 1870 by J. R. Dodge, at that time statistician of the department.

The accompanying diagram will illustrate the proportion of forest area of farm lands in the several States—the figures in the white portion of the squares representing the farm-area in acres, and those in the shaded portion the proportion of that area in forest, in each State respectively. In some of the States the farm lands comprise nearly the entire area, exclusive of lakes and streams; in others, those more recently settled, and

also some of the original 13, the unoccupied or wild lands constitute a considerable proportion of the whole area. Thus Maine has 5,835,058 acres in farms, while her area includes 22,400,000 acres of land and water. In estimating the proportion in wood land, the water surface on lakes and streams, the prairie, the ledges and other wastes incapable of producing trees, must be taken into consideration. After canvassing the facts affecting this proportion in the several States of the area exclusive of farms, one-half was assumed to be in forest in Maine, New Hampshire, Vermont, Pennsylvania, Maryland, Kentucky, Missouri, Michigan, Florida; six-tenths were taken for Arkansas, Virginia, West Virginia and Louisiana; seven-tenths for North Carolina, South Carolina, Georgia, Alabama, Mississippi and

tion of passengers to freight on the former is greater than in this country, though only 52% of the whole earnings. The operating expenses in Great Britain average 52%; in the United States, 58.40%.—Springfield Republican.

FARM LABOR AND WAGES.—Colonel Worthington, the statistician of the agricultural department, has finished his annual report on farm labor and wages, from which a number of interesting facts given below are gathered by the Tribune: The table giving the average of wages of farm laborers, with and without board, as compared with the wages paid in several branches of skilled mechanical labor, was compiled from returns made to the department last April, from which it is learned that in the Pacific and mining States and Territories, the range of monthly wages for farm laborers without board is between \$30.75 in Montana and \$22.50 in Washington Territory. Of the States east of the Mississippi, Minnesota pays her farm laborers better than any other northern State, the monthly wages with board being \$16.33, while Vermont pays only \$12.62. In the Southern States the prices paid range from \$12.26 in Louisiana to \$7.32 in South Carolina, the average being \$9.60.

BUILDING THE DAM.—We learn from the Marysville Appeal that the work of building the dam on the Yuba river has commenced. The workmen seem to have come from the four quarters. It is estimated that there will be work for 500 men for weeks to come, and although this is the busy season, it is believed that enough men can be obtained for the work. No Chinese will be employed in any capacity. The contractors expect to pay the laborers \$40 a month and board.

EARTHQUAKE IN CUBA.—A slight earthquake occurred August 20, at Mariel, twenty miles west of Havana, lasting for three seconds. The oscillations were from northeast to southwest.

saddest smiles: "I have already lunched. I have eaten half a rose. I have kept the other half for my supper."

VITALITY OF A NEWSPAPER ITEM.—A remarkable instance of the vitality of a newspaper item is given by the Christian Advocate. That journal says: A good many years ago the late Rev. John Milton Holmes, a young minister of Jersey City, preached the eighth anniversary sermon of his installation over a Congregational church. In some way it started as the eightieth anniversary sermon, and traveled all over the United States and Europe. The contradiction went lazily after it, and after awhile it died out. But four years later it sprang up again, with editorial comments, in an English paper, and after having a run there came over to this country, where it was finally killed. Meanwhile Mr. Holmes died, being about 40 years old.

A CURIOUS INCIDENT.—Mrs. Cannon, wife of Mr. Will Cannon, of Robinsonville, Tex., was on her way home from church on horseback, one evening lately, when she felt something stick her in the face, and supposing it to be a limb of a tree, threw up her hand to ward it off. While undressing for bed after her arrival home, she was horrified to find a rattlesnake in the sleeve of her dress. The reptile dropped out on the floor and was killed. The lady had not previously felt much inconvenience from the slight abrasion on her face, but it now commenced swelling, and became so painful that a physician was called in to attend her. It is supposed the snake had taken refuge in the tree, and that it hit her and transferred itself to her sleeve as she rode under it.

OPPORTUNISME is a new word in French politics just now. Rochefort and his party are opposed to opportunisme, to which dreadful quality they claim that Gambetta is a slave.

Tennessee; one-third was taken for Massachusetts, New York and New Jersey; one-fourth for Texas and Oregon; one-sixth for Wisconsin and Minnesota; one-eighth for Iowa; one-tenth for Rhode Island, Connecticut, Ohio, Indiana and Illinois; one-twelfth for California; one-twentieth for Kansas, Nebraska and Nevada.

Taking into consideration only the farm lands, the proportion of wood lands is smallest in California, being 4.1%. In order, respectively, follow Nevada, 6.4%; Nebraska, 10.2%; Kansas, 11.2%; Iowa, 16.2%; Illinois, 19.6%. The proportion increases, State by State, from the Pacific coast eastward to Indiana (39.6%), and then comes the devastation of the ax, which reduces the percentage of Ohio, a region originally forest, with the exception of small patches of prairie mainly about the headwaters of the Miami, to 31.7%. Pennsylvania has about the same proportion, or 31.9%, and New Jersey 24%.

There are only two other Western States that have percentages between 20 and 30, viz.: Minnesota, 20.6; Wisconsin, 29.3. The Eastern States (besides New Jersey) which come within the same limits are: Connecticut, 24.4; New York, 25.5; Massachusetts, 25.8; Delaware, 28; New Hampshire, 29; Vermont, 30.6. Those having between 30% and 40% of this farm area in forest are: Pennsylvania, Indiana, named above; Oregon, 31.8; Maryland, 31.8; Rhode Island, 33.7; Maine, 38.1. The States having between four and five-tenths of their farm lands in forest are three—Michigan 40.7%; Texas (the eastern portion generally wooded), 41.6%; Virginia, 45.7%. The southerly belt is the most heavily wooded portion of the country, all the States, with the exception of Virginia and Texas, having more than half of their farm-areas in wood land, and a larger portion still if the wooded wild lands should be counted in with the farm lands. The proportion in the occupied or farm areas is as follows: West Virginia, 51.1%; Arkansas, 51.4%; South Carolina, 53.2%; Georgia, 54.6%; Tennessee, 55%; Alabama, 56%; Florida, 60%; North Carolina and Mississippi, 60.6%.

Fairs and Industrial Exhibitions.

Fairs and industrial exhibitions were born of trades. The thought of exhibiting at some central locality the handiwork of a State, a nation, or of a number of nations, is coeval with the birth and growth of trade and exchange. The Olympic games of the Greeks may perhaps be considered the embryo of national fairs. In the St. Dennis fair, established in the seventh century of our era in that ancient manufacturing suburb of Paris, we may recognize the origin of world's fairs. From that time until the present, especially throughout all the centers of exchange in Central and Southern Europe, fairs have been held at more or less frequent intervals, exhibiting and revealing to man the growing genius of the world and pointing out to him the true road to comfort, to happiness and to prosperity, through the labor and genius of the mechanic, the artisan and the manufacturer. The fairs of the Middle Ages were largely instrumental in redeeming the world from the darkness of ignorance, and in establishing a general desire among the various classes of craftsmen to improve in skill and knowledge, and to advance the masses to a higher plane of human brotherhood and dignity.

But the most wonderful development connected with fairs has been made since the introduction of the steam engine and railroad. With the few roads of the early ages, and those but poorly constructed and kept, there was great difficulty in exchanging commodities among nations, except by water; while with hand labor alone the great cost of manufactured goods prevented any very large introduction of even the simplest articles for general use. The steam engine and the railroad having brought the extreme parts of individual countries and the various nations themselves into close proximity, and so greatly reduced the cost of all kinds of manufactures as to put them within easy reach of almost every family—the result has been a most wonderful degree of activity in manufactures, and such a sharp competition, that annual fairs and exhibitions have been largely changed from the commercial character which they had previously held, to schools for industrial observation and study, whereby the skill of one section or county is most readily gained by all others.

The modern industrial fair has become one of the greatest moral forces that ever impelled humanity in its rightful career of progress. "By generalizing the best methods of production they have increased the efficiency of human labor in every direction. By affording suggestions to inventive minds they have been instrumental in originating new methods, new tools, new machines and new uses of materials or implements already known. * * * By disseminating more broadly the knowledge necessary to an extensive trade they have given to capital a more secure basis of investment, to labor a more constant field of employment, and to commerce a more direct line of enterprise. Finding a world divided into nations, they have already done much to unite all nations into one world."

In no other way than by this grand mode of object-teaching could such new and extensive fields of practical action have been opened up to the human mind as have been improved during the last half century. These exhibitions have developed among the masses a spirit of investigation which has led to a greater degree of material progress within that time than had been accomplished during the previous thousand years. While the more favored intellects have been led into higher and scientific attainments, which have eclipsed all previous advances into the hidden mysteries of nature, the more ordinary ones have come to such a full understanding of the laws of mechanics, and have so developed artistic tastes, that the march of progress in this direction has manifested itself by a multiplicity of inventions and productions unprecedented in number and variety. A community of interest and thought has grown out of these industrial efforts, which has pervaded the whole civilized world, checked the conflict of national conquest and rendered the wars of the present generation the last convulsions of a pernicious system of military ambition, which is destined to give way before the all-conquering arts of peace. Industrial fairs constitute not only the greatest moral force which ever impelled humanity to progress; but their ultimate and legitimate mission is to bring about the desire of all nations—a final unity of mankind in one great industrial brotherhood, in which labor shall find ample remuneration in a constant field of employment, and capital a secure investment from the senseless clamor of idle and disturbing agrarianism.

PROPER SIZE OF HOUSE SEWERS.—An interesting series of observations has been made by Sewer Commissioner Moore, of St. Louis, to determine the necessary size of sewers to carry off house sewage exclusively, irrespective of surface drainage or storm water. The present sewerage system of St. Louis provides for all the drainage from whatsoever cause; but it has been found expedient, looking towards immediate extension, to arrange certain additions to the system for the purpose of conveying house drainage alone. A certain neighborhood was selected, through which Compton avenue sewer, with a diameter of 7½ feet, passes. On this area of 440 acres were 1,370 houses, population, 11,000. The observations were taken by con-

structing a small dam, with a section of 12-inch pipe running through it on the bottom of the sewer. All the flow in this sewer was made to pass through the small pipe, and it was found that in the middle of this day when the flow is highest, as a rule, the water was only 6½ inches deep in the small pipe. The weather and soil were dry enough to insure that nothing but the waste from the dwellings passed into the sewer. Another sewer was tried, 3½ by 4½ ft., in a fairly built up neighborhood of 155 acres, with the result that a pipe 9 inches in diameter gave a maximum depth of flow of 6½ inches, and a minimum of 4½ inches, giving an average of, say, 5½ inches. While the quantity of the flow seems small, it, however, indicates a consumption equal to about 80 gallons of water per day for every man, woman and child.—*Plumber and Sanitary Engineer.*

Electricity and Railways.

The world has been gazing toward Menlo Park, wondering if Mr. Edison is to solve this problem of moving railway trains by electricity, when suddenly it is discovered that a young inventor has been at work who has obtained patents for an electric motor which antedates any similar patents obtained or solicited by Mr. Edison. It will be a matter of much interest to the public to know that the young inventor, Mr. Stephen Dudley Field, is a nephew of the man who has placed the civilized world under perpetual obligations for his invention of the submarine telegraph. Having given mankind one of the most marvelous appliances of electricity, it must be peculiarly gratifying to Mr. Cyrus W. Field to discover that the son of his brother is likely to introduce the electric current to still other important uses.

If electricity can be made to take the place of steam upon railways, its introduction to such a use will undoubtedly be one of the most important inventions of the age. The discomforts of railway travel will be greatly reduced, while its safety will be increased. These facts awaken a profound public interest in the attempts of inventors to produce a substitute for the steam locomotive. The escape from the dust, the smoke, the heat and the noise of the ordinary locomotive, will make railway travel pleasant instead of irksome, and the impossibility of a collision of trains propelled by Mr. Field's electric motor will remove terror from the minds of the timid mortals who never take a train without apprehension of a disaster. But the economy of the new motor is what recommends it to the immediate attention of railway managers. If electricity can be used at all for the propulsion of railway trains, its cheapness will greatly enlarge the profits of railways. Requiring no fuel or oil, the cost of the electric motor will be far less than that of the complicated locomotive now in use, and its weight will be so moderate that the wear and tear to tracks will be only a fraction of that caused by the ponderous machine by which all trains are now propelled. If introduced, electric motive power may result in a cheapness of transportation which will effect results of great magnitude in commerce, giving the nation an unexpected advantage in the transportation of its products to supply the markets of the world.

However incredulous the public may be as to the possibility of moving the heavy freight trains of surface roads by electricity, it must be confessed that the introduction of an electric motor upon our elevated railways seems feasible, and nowhere else is there such a demand for a substitute for the heavy, dripping, smoking, dirty, noisy steam locomotive. The owners of the elevated railways will be eager to save the \$500,000 or more annually the introduction of the electric motor promises, but they will also take pleasure in promoting the comfort and safety of their patrons by adopting the invention as soon as its utility is demonstrated. It is a matter for congratulation that they are disposed to immediately give Mr. Field's electric motor a full and complete trial.—*N. Y. Mail.*

THE PORT OF GUAYMAS.—This coming rival of San Francisco is thus described by a correspondent of the Prescott (Arizona) *Miner*: The port of Guaymas is situated on the eastern side of the Gulf of California (called on Spanish maps by its original name of the Gulf or Sea of Cortez). The harbor is safe at all seasons, and will accommodate vessels of all sizes; those of deepest draft lie in the outer anchorage; small coasters come in near the Custom House wharf. The population is about 5,000. The commerce consists of the import of foreign dry goods, groceries, hardware, machinery, lumber, wine and spirits, from San Francisco and Europe, and the export of hides and treasure to San Francisco. The traffic coastwise consists principally of the export of flour to southern ports and the import of coffee, sugar, etc., from the south. The vicinity of Guaymas is sterile. Water is at present supplied by water carts, which are filled at wells on the outskirts of the town. A project is entertained of bringing a supply in pipes from the Rancho of San Jose de Guaymas, about nine miles from here, the necessary surveys and plans for which are now being made. The climate is very hot in summer, and in winter cool, without frost in the southern part of the State. The rainfall is very low on the coast, but much more abundant in the agricultural districts. Guaymas is very healthy, the death-rate being exceptionally small.

Encouraging.

At a meeting of the American Bankers' Association in Saratoga on the 11th inst., George R. Gibson, of California, in his address, after reviewing the growth and prospects of the railroads of the Pacific Coast, concluded as follows: In California the internal industries are generally prosperous and productive, and the wheat crop this year will be unprecedented. Last year the Pacific States closely approximated Russia in its export to Great Britain, and this year they will far exceed it. The acreage is 20 per cent. above the average, and present appearances indicate that California alone will yield 50,000,000 bushels, requiring a wheat fleet of 350 vessels to move the surplus. When California wheat was first introduced into the foreign markets it commanded two shillings per quarter more than any other wheat, but negligence in harvesting and shipping has reversed this premium, and it now brings about two shillings less. This has been observed by the Produce Exchange, which will endeavor to remedy the defect which involves an annual loss of \$3,000,000 to the farmers of the State. The revenue from its fields, forests, herds, fisheries, orchards, shipping, gold, silver and quick-silver mines is a direct creation of wealth, and must serve to continually enrich its energetic population. Business stagnation, which is of periodic occurrence in all commercial countries, and pernicious legislation, may temporarily impede, but cannot defeat the splendid destiny of that Empire by the western sea, with its unrivalled resources of soil and mines, its genial climate and commanding position at the gateway of Asiatic commerce.

PETROLEUM IN ITALY.—In a letter published in the *Pungolo*, attention is called to the existence of petroleum in the Province of Basilicata. It is by no means a recent discovery, for the writer himself says that when he was at Marsiconovo, 40 years ago, examining the asphalt which was found there in abundance and of excellent quality, he observed large bubbles of petroleum floating on the surface of some streams. On digging for the foundations of a magazine in the same district, there was a strong gush of petroleum, but the source was closed, as there were no roads nor facilities of transport. No one thought of utilizing this hidden wealth (as there is, I believe, much of the same description in Basilicata and the neighboring provinces), for there were no roads, communal, provincial or national; and had the same system of government been continued, the ground might have yet been undisturbed. Signor Venini-Poma, who has substituted petroleum for coal in heating steam boilers, claims to be the first who so applied it. Prof. Casola, however, an eminent chemist whom I well remember, was the author, it is asserted, of the system of locomotion by petroleum. He had an establishment in the Largo di Castello, which was filled with specimens of the various kinds of coal or asphalt found in the far south, and there he made many experiments and proved the locomotive power of petroleum. It was Prof. Casola who discovered the petroleum of S. Giovanni Incarico, and he would have done much with enlightened encouragement to have improved the economic conditions, especially of southern Italy; but, thwarted and discouraged, he died of a broken heart. I knew him and many of the facts now brought before the public, and I think that it is time for speculators to visit those districts, and study how the valuable products lying hid beneath the soil could be easily and economically utilized.—*London Mining Journal.*

"HAVANA" CIGARS FROM PAPER.—The straw paper manufacturers of the Chatham portion of Columbia county, N. Y., have for many years been aware that their product has nearly all gone South, and been used in Cuba as fillers for cigars. None of them manufacture specially with this end in view, although their paper is well adapted for "bogus" cigar making. The paper used for the purpose indicated is of the lightest weight (7 to 7½ lbs.) it is possible to make. There is one mill in the county located at Queechy (town of Canaan), which manufactures the straw paper expressly for wrappers—not fillers. The Queechy Paper Co.'s paper mill is situated on a creek but a short distance below a lake, and being at the head of the stream, the water is of much greater purity, and hence their ability to produce the desired article of paper. The straw paper used in filling the Havana cigars is saturated with a decoction prepared from the stem and refuse of Havana seed leaf, mingled with which are extracts of liquorice root, senna, etc. The paper is so skillfully stamped to resemble the tobacco leaves, the very veins of the leaf being perfectly imitated, that it can seldom, if ever, be detected from the genuine article.—*Paper World.*

A NEW and peculiar variety of coal is described in the *Neves Jahrbuch für Mineralogie*. It is found on the northwestern bank of Lake Ouega, Russia, in strata stated to belong to the Huronian formation. It differs in its physical, as well as its chemical, properties both from anthracite and graphite. Pure varieties show a strong metallic luster, which remains even after exposure to a dull red. Its hardness varies from 3.5 to 4, and its density at 4°C is 1.841. It is highly hygroscopic, an analysis yielding: Carbon, 95.50; hydrogen, 0.40; nitro-

gen, 0.41; water, 7.76; and ash, 1.01. When free from water the percentage of carbon runs up to 98.11%, so that it is richer in carbon than anthracite, though it contains less hydrogen, no oxygen and much nitrogen. The "black earth" from Olonez is distinguished from graphite, which it resembles much, by the fact that it does not yield graphitic acid or "Brody's graphite" with a mixture of nitric and sulphuric acids, nor does it burn as rapidly as graphite.

118 and 120 Market Street, and 15 and 17 California St., San Francisco.

We would call the special attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our stock of Clay Crucibles, Mullers, Dry Cups, etc., manufactured by the Patent Plumbago Crucible Co., of London, England, for which we have been made Sole Agents for the Pacific Coast. Circulars with prices will be sent upon application.

Also, to our large and well adapted stock of

Assayers' Materials & Chemical Apparatus,

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.

Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application.

JOHN TAYLOR & CO.

**W. BRUCKNER'S
ROASTING FURNACE
AND
Ore Pulverizers.**

(Awarded the Premium Gold Medal at Naples, Italy.)

The furnace is especially adapted for roasting rebellious ores; there are more than fifty in use in Colorado, giving perfect satisfaction.

The Ore Pulverizer is built in different sizes. It is preferable to Stamp Mills because it requires less power and less repairs than Stamps. No extra expense for setting up, and no foundation. Less weight and less cost than stamps. Furnished also in sections for packing.

NOW READY!

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW ON SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Quarto. 234 Illustrations.

By ROBERT GRIMSHAW, Ph.D., M.E.,

Member of the Jury on Wood-working Machinery at Paris Exposition of 1878.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small band, ash, Mulay, jig, drag, circular, cylinder and hand Saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, iron, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, swaging, gumming, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 36 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copiously indexed. Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the price is this date made \$2.50, postage paid.

ROBERT GRIMSHAW,

624, 625 and 628 Market Street, Philadelphia

March 10 1880.

Mr. Wilcox sold similar engines at \$300 each. I have taken this engine as an attorney fee, and will sell it for this price and WARRANT it. Address

MANUEL EYRE,

Law Office, No. 630 Clay St., room 25, S. F.

Some fine sunny offices (next to the PRESS office), to rent (at very reasonable rates), by Dewey & Co., at 202 Sansome street, corner of Pine.

Engraving. Superior Wood and Metal Engraving, Electrotyping and Stereotyping done at the office of the MINING AND SCIENTIFIC PRESS, San Francisco, at favorable rates

Traveling Agents.

We want several canvassing agents who will make their business to solicit subscriptions and advertising for our first-class progressive newspapers. Men of ability and experience can secure good pay and permanent employment. Send references and state your past occupation, etc., to the publishers of this paper.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

DIVIDEND NOTICE.

OFFICE OF THE

Eureka Consolidated Mining Company,

Nevada Block, Room 87, S. F., August 16, 1880.

At a meeting of the Board of Directors of the above-named Company, held this day, a dividend No. (58), of Fifty cents per share was declared, payable on FRIDAY, the 20th day of August, 1880. Transfer books closed until the 21st instant. W. W. TRAYLOR, Secretary.

Gover Mining and Milling Company.

Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.

Notice is hereby given that at a meeting of the Directors held on the Eleventh day of August, 1880, an assessment (No. 43) of 20 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 402 Front street, room 8, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Thirtieth day of September, 1880, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the Eleventh day of October, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

W. O. WILSON, Secretary.
Office—402 Front street, room 8, San Francisco, California.

New Book on the Comstock.

The attention of MINING ENGINEERS and EXPERTS
is called to the new work by JOHN A. CHURCH, E. M. Ph.
D., on "The Comstock Lode, its Formation and History."
This very exhaustive treatise on this famous lode is fully
illustrated with diagrams and colored charts showing sec-
tions, ore bodies, etc., and will be of great interest and per-
manent value for reference. DEWEY & Co., Publishers of
the MINING AND SCIENTIFIC PRESS, are sole agents for the
sale of the work. Mr. E. M. SLEATOR will act as their
agent, and call on Mining Engineers and those interested in
the great lode in this city with a copy of the book for their
inspection.

FRUE'S ORE CONCENTRATOR OR VANNER.

CRUSHING ROLLERS. SAMPLE GRINDERS.

Howell's Improved White Roasting Cylinders,
REVOLVING CYLINDERS AND ORE DRYERS.
Hoisting and Pumping Machinery.

STEIGER & KERR'S CONTINUOUS DISCHARGE AND GRINDING PAN.

This pan is designed to receive ore direct from a rock breaker, and reduces it to the fineness necessary for amalgamation, thus taking the place of the ordinary stamp battery. The cost of this Mill places it within the reach of all; and one point of advantage not to be overlooked is the fact that the cost of erection, which adds so much to the expense of the stamp mill, after it leaves the foundry is, in this case, reduced to a fraction, as the Mill is complete in itself, and requires no expensive foundations, bed logs, battery frames, etc., but can be placed in position in a few hours after it arrives on the ground, without the aid of skilled labor. This simple arrangement, durable as it is, is a most important improvement in the working of gold ores, as it enables parties to construct and erect a mill at half the cost of a stamp mill, and with a great saving of time, and size of mill building. Each pan is capable of reducing 10 tons of average ore in 24 hours, the ore being first broken in a rock breaker, small enough to go through a half-inch screen. There is an important point in the action of this Mill, to which we desire to call the attention of miners and millmen. We allude to the grinding and scouring action on the gold before it is discharged. The value of this point cannot be over estimated, and it is not necessary to do more than mention the fact, as it will be at once recognized by all competent millmen who examine the pan in operation, and especially by those who have had to deal with tarnished or rusty gold, as it is commonly called, and which is often encountered in our mines, and which is such a cause of loss. The pan of feeding is the same as in the stamp mill, either an ore feeder or hand feeding being adopted, as may be desired. Parties interested in mining and mills can see the Pan in operation by calling at the OCCIDENTAL FOUNDRY, STEIGER & KERR, 137 First St., S. F.

RICKARD & DURDEN'S Anti-Scale Compound, FOR THE PREVENTION AND REMOVAL OF INCRUSTATION IN STEAM BOILERS.

Ten years' trial in widely separated localities, having demonstrated the value of this invention, and its applicability to different qualities of waters, we now offer it to Engineers and Steam Boiler Owners, with the fullest confidence as to the result.

Scientific Press

Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address **DEWEY & CO.,** Patent Agents, 202 Sansome St., S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

GIANT POWDER

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS.

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive

Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. 2 1/2 Triple Force Caps and all Grades of Fuse.

VOLUME XLII
Number 10.

The Inter-Oceanic Ship Railway.

Obstacles in the Way of New Enterprises and Inventions, Strains upon Ships, Etc.

That ships of the largest size with their cargoes, can readily be taken from the water, quickly transported by rail across the Isthmus and launched once more upon the ocean, is unquestionable. It is unfair and uncomplimentary to assume that any enlightened community is ignorant of this fact, and we enter into no argument to prove what, in the light of recent achievements, is almost a self-evident proposition. Whether it is wise thus to transport ships and cargoes is another question, concerning which no thoughtful person need be told there must be diversity of opinion. There is an ultra-conservative element in all communities strongly inclined to resist any innovation upon the good old way. It looks upon the suggestion of an improved method, process or machine as an offensive assumption of superior wisdom severely to be reproached and frowned upon. What if the man has devoted half a lifetime to the solution of his problem? So much the worse. Unusual persistency in the investigation of a single subject, especially in a new direction, over an unheated tract, is set down as evidence of mental aberration—proof positive of an unsound mind. The opinion of such a person may be of some value on other subjects, but, in the line of his speciality, before its reduction to practice, or in other words, in what this unprogressive element is pleased to term his hobby, it must not be permitted to weigh for a moment against the dicta of those who have given this matter little if any previous thought. A wise and prudent conservatism is the balance wheel and safeguard of society; and for this we have the greatest respect. But, there is a blind, unreasoning conservatism that would block the wheels and stay the oar of progress evermore. It bitterly opposed Stephenson's efforts for the introduction of the railway. It chafed lustily when Fulton's little steamer stopped a few yards from the shore and drifted down the stream. It gave audible vent to its disappointment when the boat started once more on its way, and hushed its voice in sadness as she steamed out of sight.

The electric telegraph was invented by Morse in 1832—publicly exhibited, and recommended by scientific men in 1835, again in 1836. Exhibited before the Franklin Institute and warmly endorsed thereby in 1837. Soon after exhibited before the President, Cabinet and members of Congress; appropriation therefor was recommended by Committee on Commerce in 1838; obtained in 1843, and on the 27th of May, 1844, the first commercial line was completed, and the first message, "What hath God Wrought?" transmitted from Washington to Baltimore, by Miss Anna Elsworth.

The numerous successful experiments we have specified over lines varying from a fourth of a mile to ten miles in extent, so convincing to those who understood the subject, had, as is often the case, a directly contrary effect upon the element of which we are speaking, which set Morse down as a visionary, and his telegraph as a humbug; because without capital and with his crude apparatus made out of a picture frame and old clock, he did not immediately achieve a financial success. But the value of his invention was appreciated and warmly endorsed by scientific men from the start. Unfortunately these men, in this country, are seldom capitalists, and mankind has a sovereign contempt for brain unassociated with coin; indeed, cannot often be convinced of its existence. It has little faith in the reports of experts, or in the certificates or affidavits of those who have made tests, unless these reports, certificates and affidavits are backed by the cabalistic signs of £. s. d.; often not even then. Ample evidence of this fact lies thickly strewn all along the pathway of progress.

For nearly 14 years the sneering crowd of doubting Thomases had held the great inventor at bay, and probably would have held him to the day of his death, had there not been a few scientific men in Congress.

Similar remarks apply to all important inven-

tions and all great enterprises. Witness the Overland railway, Susquehanna, Mississippi jetties, St. Louis bridge—in short, all propositions emanating from those who, by dint of hard labor and patient investigation, are emboldened to claim, and have a right to claim, a knowledge of what they are about. This unprogressive element seems to feel personally aggrieved therewith. Why should this man investigate the subject until he knows more about it than we do? It is not true. He has not done so. Perish the thought! There are others who exam-

they not unfrequently discover their error when the opportunity they ought to have embraced has ceased to exist, and in this, as in other things, they pay for their learning.

This unprogressive element learns nothing from experience. It is never more ready to pronounce its dictum than upon subjects concerning which its ignorance is most profound. It is an obstacle that cannot be avoided. It confronts the inventor at every turn; stands ever in the pathway of progress, and must always be taken into consideration by those who

ever of the actual facts, with a shrug, a wink, a snicker, and a grin, it consigns for the time being many important enterprises, scores of useful inventions, to the limbo of forgotten things. But there are men who rise like Banquo's ghost, and down at no one's bidding. They work on until they reach the end of men of nerves and men of means, who are willing to listen and competent to judge, for there are such men, who reason in this wise: This man appears to be moderately intelligent. There is about him no apparent evidence of insanity or imbecility. He has devoted much time and some money to this investigation of his subject, and claims to understand it. After all this investigation it would be strange if he has not learned something. He may have hit upon something valuable. Such things have happened and may happen again. We can afford to examine a hundred schemes for the sake of finding a single good one. Let us hear what he has to say. In most cases we find the man is mistaken. He is ignorant of the mechanical or engineering principles lying at the foundation of what he is attempting to do, though perhaps a good workman and skillful in his line. He has not made himself familiar with the present state of the art. He is working out an old idea that has been tried and abandoned, or has reinvented something already in successful operation. He has introduced some doubtful element, or some principle that has not been sufficiently tested; or his scheme may be good, but there are others of the same character that are better. His plan may be ingenious and skillfully worked out, but there is no money in it. One man wants to get up a line of street cars where there is not sufficient population to sustain it. Another has invented a machine which he says will do a certain amount of work with 5-horse power. A moment's calculation shows that the work alone, irrespective of friction, will require 20-horse power. Another has invented, and it is astonishing how many have invented, perpetual motion. This is a mechanical impossibility. Another has invented an apparatus for making post-holes. Take that to our friend Agricola; we are not in the post-hole business. Another has an invention for exterminating rattlesnakes; but where can we get the snakes? A few minutes' courteous attention is sufficient for all such cases as these. Occasionally a matter comes up that requires a wise investigation. If it is at all in the line of our possible interest, and if successful, would be important, and especially if it is in the line of the projector's business or profession, we listen to all he has to offer, and, if in doubt, call in an expert, requiring him to present his doubts or objections, if any he has, to the projector, and give him an opportunity, if he can, to remove them. This, of course, involves some labor; but many a good thing is lost by refusing to look at it. By and by the right thing comes along, and we are rewarded for all our trouble. This would seem to be a reasonable view to take of the matter; but those who take this view are rare, and it is hard to find them. Great persistency, therefore, is necessary on the part of those who wish to accomplish anything, however important, for which they, themselves, have not the requisite means. But, persistency is not proof of wisdom. There are those whose persistency would "pierce the dull, cold ear of death," who yet know nothing whatever of the subject outside of their own experience, and this, when the experience of hundreds of men, and of a thousand years, is within our reach, is a matter of little importance. But these men make their way by sheer persistency. Unable to demonstrate their propositions, it is with the uninvestigating element, comprising by far the greater portion of the race, that they find their opportunity. Hundreds of thousands of dollars are annually squandered in undertakings that any person reasonably familiar with the subject can see at a glance to be unsound. Nor is it sufficient to examine a single enterprise or a single machine, and judge from that alone. Many an enterprise, many a machine judged by itself, may be a success, yet compared with other enterprises or other machines of a similar character, is an utter failure. Hence, the ship railway should be compared with the ship canal; steamships with vessels propelled by sail, and so on.

Engineering problems and mechanical im-

line a new invention, understand and appreciate its value, but discover that, for every ten dollars that they could save by its use, the inventor might make one—and they "go" for that one. Instead of feeling that the inventor is rendering them the great service of largely reducing their expenses, they think he is robbing them of one-eleventh of their legitimate savings; and rather than submit to this, they will use the old machines, forgetting that by so doing they mulct themselves ten dollars to the inventor's one. But, these patient, persistent, investigating workers have a strange habit of succeeding at last, and posterity "writes down as asses" those who attempted to block their way, though it cannot be denied that inventors, as a rule, see things at first only from their own stand point, and are so unreasonable that even liberal capitalists can do nothing with them, and

would inaugurate any great enterprise or introduce anything new, or that may be supposed to be new. It is well that inventors do not realize this fact until their inventions are completed, or they would be rarer than the angel visits popularly supposed to be "few and far between." This element seldom appeals to the public through the press. It is far too shrewd for that. It cannot conceal from itself its ignorance. It knows that its sophisms would be punctured and collapse like a bag of wind. But its influence is none the less felt. It shrugs its shoulders and refuses to invest. It hopes it is all right, but, with a knowing wink, fears there is something wrong. Thinks it would be just as well to have the thing tested at some one else's expense—and so on, *ad infinitum*, *ad nauseam*. Without one word of argument, without investigation, with no knowledge what-

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EBS

Mines in and around the Silver Peak Salt Basin, Nevada.

EDITORS PRESS:—Dull enough for these many years have been mining matters in this remote corner of Nevada, notwithstanding this may be considered one of the oldest camps in this part of the State. The mines in the Red Mountain district adjoining this on the west were discovered in 1863, causing at the time no little sensation because of their obvious value. The next year the Great Salt Basin Mining and Milling Co. put up there a 3-stamp mill for reducing the ores, which are gold bearing. That year the silver mines in this district were discovered, the same company having put up here a 10-stamp mill in 1865. After a short but tolerably successful run these mills came to a standstill, and with some brief exceptions, have remained idle ever since, their suspension having been due to had management and the great cost that then attended mining here. This property, which is a very extensive one, has lately passed into the hands of new owners, who, it is said, will shortly resume operations upon it. Included in this estate are nearly 100 different mining locations, 1,000 acres of woodland, two mills, houses, shops, and other outbuildings in great number, besides quite an extended system of railroads connecting their mills with the mines. Although a great deal of money has been expended here, much of it foolishly, these mines under a good management could be made to pay handsomely and perhaps very largely. It seems a pity that such a property should have been suffered to stand idle so long. It employed at one time over 100 men, and with reduction works adequate to its productive capacities, could, no doubt, give profitable employment to twice that number.

Very different from that of Silver Peak is the history of

The Montezuma District

Lying over against this in the high range of mountains, 15 miles to the east. Little has ever been heard of it. It has no place on most of our maps; capital has never gone to its aid; it has taken care of itself—paid its own bills and enriched in a small way a good many of our pioneer miners. What values in the shape of ores and bullion have gone out of the district I have no means of knowing with much exactness—half a million certain—possibly twice that much. During its earlier history all the ore raised there was shipped away, mostly to Austin, I think, to which place its carriage must have amounted to \$100 per ton, at least. It must have been good ore to stand such a transportation tariff, and leave margin for profit after defraying costs of extraction, reduction, etc. In their upper portions these Montezuma lodes carry a sulphuret mixed with a chloride ore which as depth is gained runs into galena and a carbonate of lead containing from \$40 to \$200 silver per ton, and from 20% to 40% lead. At a central point in the district a 10-stamp mill was put up some years ago. This mill has performed good service, having, with the aid of a Howell roaster, reduced a prodigious quantity of ore, making, perhaps, as large net earnings as any small mill ever erected in Nevada. But for the reason above stated, much of the ore here to insure its economical treatment requires now a smelting furnace, persistence in its reduction by milling involving a large percentage of loss. It is reported that the company, who own most of the property in that district, will shortly put up a large sized smelter on a site convenient to their mines. Should this be done it will revive business at Montezuma, where, from the want of a structure of this kind, it has for several years past been languishing. Montezuma is the best wooded district in this part of the State, timber there covering a great area, the growth being dense and many of the trees reaching a large size. There is more water there too, and of better quality than is common in this section of country. If they get smelters we may look for renewed activity and a long-continued prosperity over at Montezuma.

A Slight Awakening—Oppressive Transportation—Relief Through a Railroad.

There is some revival of the mining interests all around here; in every direction there is more stir than has been noticeable for many years past. This grows out of a variety of causes. In the first place, the mines themselves are good—the lodes often large and generally of a permanent kind, while the ores, which carry either gold or silver and sometimes both, are uniformly of high grade. But what has most served to awaken new interest in mining here is the promise of a railroad soon to connect these districts with the outside world. There is not in all Nevada a more difficult region to be reached with heavy freights than this. This camp, the center of a great mining territory, is 225 miles from Dayton, nearest point on any railroad. The intervening country is dry, barren and much of it sandy, and so continues to be for a long distance beyond this point. With the exception of hay, vegetables, fuel and some little grain raised for horse feed, nearly everything required for human use, wear or subsistence, as well as for mining purposes, has to be hauled by team over this long stretch of desert,

having before being transferred to wagons undergone several hundred miles of railroad transportation. Every commodity comes to us then loaded down with freight charges that very often greatly exceeds its first cost. The freight charges on a ton of goods, machinery included, from San Francisco to this place amount now to over \$120, the rates paid on most of the machinery brought in here having been much larger. That under those oppressive burdens such extensive improvements should have been made, and the mines been so much developed as they have been argues a great richness for the ores here disposed of.

Should this road be built, or rather extended as far south as this point, it would infuse new life into the mining industries throughout this section of Nevada as well as the adjoining mining districts of California. The impression obtained here at one time that this road was to terminate at Walker Lake, but latterly we hear that it is to be carried on into the neighborhood of Columbus, which would bring it within 45 miles of this place, and about the same distance of Montezuma. To stop it at Walker Lake would evince a short-sighted policy on the part of the builders, as the worst and widest part of the desert lies between Columbus and that point. While the country from here to the Lake is sandy and sterile, it is generally favorable for railroad construction. The road brought on into the mines could not fail to prove a profitable investment, while a halt halfway might imperil its success. This road should therefore be built without halt and with as little delay as possible as far as Candelaria at least, if not the few additional miles further on to Columbus. This would bring it terminus to a point central to a great many important mining districts, as well as to the extensive deposits of borax that exist in the neighborhood.

Concerning the mines in the Columbus district and some less important outlying localities in this part of the State, you may look for something when you next hear from

SILVER PEAK.

Silver Peak, Aug. 25, 1886.

Into the Bonanza Group.

The north header of the Suro tunnel has passed through the Con. Virginia and California mines, and is fast nearing the point where it will connect with the Ophir, being at present in the Golden Gate ground, which adjoins the Ophir and Mexican on the east. The course of the tunnel will continue a little east of north until it connects with the Ophir, when it will hear more to the eastward for a connection with the Union shaft, thus passing diagonally through the Golden Gate ground at a depth of 1,600 ft. below the surface. Its connection with the Union shaft will be a very important one and anxiously looked for, as it will be of invaluable assistance in the way of drainage to the new bonanza deposits now being developed in the Sierra Nevada and Union ground.

It is easy to see that the Golden Gate, located in the very midst of these valuable developments, and with the Suro tunnel now making its way directly through it, is rather of an interesting piece of property at the present time, as the tunnel has over a thousand feet yet to go in order to reach the Union shaft, and all the way through the Golden Gate ground, passing directly beneath the heavy and prominent croppings in the cemetery, just north of Virginia. The Golden Gate Company, formerly the old Vermont Con., have their title fully perfected and covered by United States patent. They now propose to resume sinking their large new three-compartment working shaft down to a connection with the tunnel, and have levied an assessment for that purpose. They have excellent prospects already, but are going after their full share of the good things at that point.—Enterprise.

WILL POWER AND FASTING.—A young mechanic, condemned to four years' imprisonment in Italy, has managed to starve himself to death in 30 days. Dr. Tanner fasted 40, and is none the worse for it. But the Italian would die, while Tanner would live—a very important difference in the two cases. There used to be a theory that people need not die at all if their wills were strong enough. Absurd as it was, it contained a grain of truth. Weak-willed men succumb to accidents or attacks of disease, while men of strong will live through. The experience of army surgeons abounds in instances of remarkable recoveries of plucky fellows who seemed to have no chance of fighting off death, and of equally remarkable deaths of soldiers with flabby resolution who succumbed to slight wounds. On the whole, the mechanic's case is rather more interesting than Dr. Tanner's. Both confute a host of medical writers, who say that nine days' abstinence from food will kill a healthy man; but the young Italian has demonstrated that a man who tries to kill himself by the starvation process, may have a whole month finishing the job.—N. Y. Tribune.

REMARKABLE LACE WORK.—One of the chief lace-makers of Brussels is at work upon the veil and train which are to be worn by the Princess Stephanie, the daughter of the King of Belgium, upon her marriage to the prince imperial of Austria. Three hundred women have already been four months employed upon this veil and train, which will be more than three yards wide by five yards long. The lace is point d'aiguille, with the arms of Belgium and Austria on the border, and will be a wedding gift from the city of Brussels to the bride.

METEOROLOGICAL.

Application to the Distribution of Rain.

[By PROF. JOHN LE CONTE.]

The general physical considerations which have been enumerated afford a satisfactory explanation of the several features of the abnormal distribution of rain along the Pacific coast.

1. Increase of rainfall with increase of latitude.—It is evident that as we go north along the coast the temperature of the surface waters of the ocean (the vapor-furnishing apparatus), through the influence of the "Kuro-Sivo," is rendered comparatively warm; and, at the same time, the temperature of the land (the condensing apparatus), especially during the winter (the rainy season), diminishes with increasing latitudes. Hence, during the rainy season, or winter months, this cause must tend, as we advance toward Alaska, to progressively augment the excess of the temperature of the ocean above that of the adjacent land—the vapor-furnishing source above that of the condensing apparatus, thereby increasing the amount of precipitation along the northern portions of the coast.

2. Sudden increase of rainfall near latitude 41°.—This is a striking but very puzzling fact. We are not yet prepared to offer any satisfactory explanation of it. So far as we know there are no observations indicating any sharp and sudden depression in the temperature of the ocean waters just at Cape Mendocino. A careful study of the direction of the winds at this portion of the coast might throw some light on this point. A most important agent in the production of this anomaly in rainfall is, doubtless, to be found in the hypsometric relations of the land lying west of the Sierra Nevada mountains to the contiguous sea. The crowding of these lofty mountain ranges toward the shore line, which occurs just north of Cape Mendocino, must evidently tend to augment the rainfall at this portion of the coast. The following numbers indicate, approximately, the distances of the crest of Sierra Nevada from the shores of the Pacific ocean: At latitude 39°, along the parallel, 190 miles; at latitude 40° 30' (Lassen's Peak), along the parallel, 140 miles; at latitude 41° 30' (Mount Shasta), along the parallel, 94 miles.

3. No summer rains between latitude 33° and 41°.—This remarkable feature of the climate of this coast is clearly due to the excess of temperature of the adjacent land, during the summer, above that of the cool ocean on the west. This condition of things, while it augments the force of the west winds, renders the precipitation of the aqueous vapors of small tension, which they sweep from the cool ocean to the hot interior, a physical impossibility, since they are being carried to a region of higher temperature. Further north, along the coasts of Oregon, Washington Territory, and Alaska, the presence of a comparatively warm ocean, renders the conditions more favorable for summer rains.

4. Winter rains south of latitude 41°.—Along this portion of the Pacific coast, in consequence of the abnormal coolness of the ocean, the adjacent lands, even during the winter season, scarcely ever become colder than the contiguous sea. At this season of the year, while the monsoon features of the winds of this section of the coast disappear, yet we have presented the anomalous fact, that when the winds blow from the ocean it never rains. This is evidently due to the low temperature of the sea, which can only furnish vapor of feeble tension. The true rain-bearing winds come from the south and the southeast, bringing the warm vapors of high tension from the Gulf of California. These vapor-laden, warm south-east winds from the region of the Gulf of California, and the western coast of Lower California, deposit a very small amount of rain in the warm latitude of San Diego (33°), but precipitate their moisture gradually more and more copiously on their way to the higher and colder latitudes. It is a well-established fact, that near San Francisco, during the rainy season, whenever the wind veers to the west, and blows from the cool ocean, the rain speedily ceases, and it clears off. Further north, along the coast, where the influence of the "Kuro-Sivo" is felt, the sea-winds during the winter resume, to a greater or less extent, their normal functions, and become rain-bearing winds.

5. Less rain in the great valleys than on the coast.—This is the normal condition of things, since it is evident that the interposition of the coast ranges must tend to cut off more or less of the vapors from the interior valleys.

6. Maximum rainfall on the western slopes of the Sierra Nevada.—After the vapor-bearing winds have passed across the coast ranges and the great valleys, they reach the western slopes of the Sierra Nevada mountains. This high mountain range, and its cold, snow-clad sides, acting as powerful condensers, extract from the southerly winds the load of moisture which they bring from the regions of maximum evaporation in the Pacific ocean. This burden of moisture is almost entirely unloaded in passing over the land lying to the seaward and especially over the cold flanks of these lofty mountains, so that comparatively little is left for de-

posit on the arid plains of the Great Basin. On the western slopes of the Sierra Nevada we find a precipitation, which, following the usual law for windward mountain flanks, augments with increasing altitude, and attains a maximum at about from 5,000 to 7,000 ft. Lacustrine Basins West of Rocky Mountains.

After this digression on climatology, rainfall, etc., we now resume the consideration of the distribution of lakes west of the Rocky mountains. From the topographical sketch previously given, it is evident that there are three lacustrine basins lying west of the Rocky mountains, viz:

1. The Salt Lake basin, near the western slope of the Wahatch mountains.

2. The Humboldt basin, near the eastern slope of the Sierra Nevada and Cascade mountains.

3. The great valleys, lying between the Sierra Nevada and Cascade mountains on the east, and the coast ranges on the west. Most of the lakes of the Salt Lake and Humboldt basins are without outlets, and consequently their waters are more or less highly charged with saline matters. This is evidently due to the small amount of rain and snow supplied to these arid basins in recent geological times. The lakes of the great valleys have outlets, at least during the rainy season. For example, Tulare lake ordinarily has no outlet, but at high water its surplus flows through a slough into the San Joaquin river. Near this lake are numerous shallow lacustrine depressions, some of them at present designated as dry lakes, which contain more or less water during the wet season.

Table.

In the following table the lakes are grouped in conformity with the foregoing topographical divisions, commencing at the north and advancing south in each division:

Lakes in U. S. West of Rocky Mountains.

Salt Lake Basin.	Max. Length in Miles.	Max. Width in Miles.	Approx. Area in Sq. Miles.	Height of Surface above Sea Level in Feet.	Max. Depth in Feet.	Height of Bottom above Sea Level in Feet.

Buena Vista.....	9	5	25
Kern.....	8	4	13	282	17	205

A glance at the foregoing table is sufficient to disclose two facts: 1st, the great deficiency of physical data in relation to our western lakes, and 2d, the remarkable shallowness of all the lakes occupying the three lacustrine basins.

BLADDERS OF FISHES.—In a recent note to the Paris Academy, Prof. Marangoni gives the results he has arrived at in a study of the swimming bladder. He states, first, that it is the organ which regulates the migration of fishes, those fishes that are without it not migrating from bottoms of little depth, where they find tepid water; while fishes which have a bladder are such as live in deep, cold water, and migrate to deposit their ova in warmer water near the surface. Next, fishes do not rise like the Cartesian diver (in the well-known experiment), and they have to counteract the influence of their swimming bladder with their fins. If some small dead and living fishes he put in a vessel three-quarters full of water and the air be compressed or rarefied, one finds in the former case the dead fish descend, while the living ones rise, head in advance, to the surface. Rarefying has the opposite effect. Fishes have reason to fear the passive influences due to hydrostatic pressure; when fished from a great depth their bladder is often found to be ruptured. Thirdly, the swimming bladder produces in fishes a two-fold instability—one of level, the other of position. A fish, having once adapted its bladder to live in a certain depth, may, through the slightest variation of pressure, be either forced downward or upward, and thus they are in unstable equilibrium as to level. As to position, the bladder being in the ventral region, the center of gravity is above the center of pressure, so that fishes are always threatened with inversion; and, indeed, they take the inverted position when dead or dying. This double instability forces fishes to a continual gymnastic movement, and doubtless helps to render them strong and agile. The most agile of terrestrial animals are also those which have least stability.

MECHANICAL PROGRESS.

To Obtain Well Defined Castings.

To obtain sharper and better defined castings, Messrs. Thorp and Tasker, of Whitefield, Lancashire, England, enclose the mold or molding box within a chamber, in which a suitable degree of vacuum can be obtained, and they run in the metal in vacuo and afterwards admit air or gas into the chamber. In the apparatus they have devised for the purpose the molding box is enclosed in a metal chamber, which is provided with a lid or door, the meeting surfaces being planed or faced, so that a suitably air-tight joint is obtained when the door is closed, with or without the interposition of a ring or of packing, as preferred, or found to be most efficient. A shaft to carry a crucible or pot to hold the melted metal, passes into the interior of the chamber, and is provided with handles or with arrangements for tilting the said crucible or pot. A sight hole closed with glass, or two or more of such holes, is or are formed in said door or in any suitable situation in the walls of the chamber, so that the progress of the running in may be inspected. The said chamber is connected with a vacuum chamber, in which a degree of vacuum is produced by means of an air-pump or of air-pumps, or by other suitable means. When the arrangements for the running are completed the door of the molding chamber is closed, and the communication with the vacuum chamber is opened. The metal is then run into the mold, and air is admitted into the molding chamber. They prefer to use a two-way cock, which, when turned to shut off the connection with the vacuum chamber, opens a passage for the admission of air to the molding chamber. The last named chamber may be large enough to contain more than one molding box. They may connect said chamber directly with the air-pump, so as to dispense with the vacuum chamber, or employ the air-pump to increase the tension of the vacuum partly formed by the said vacuum chamber. In place of the crucible or pot being enclosed within the chamber they may pour the metal into a passage leading from the outside to the inside of the chamber, or into a container communicating with the interior of the chamber or with the interior of the mold, the atmospheric pressure forcing the metal into the chamber or mold, when a plug closing the passage is withdrawn or eased, or when the passage is otherwise opened.

A Substitute for the Crank.

A device has recently been patented by Mr. Samuel W. Hanson, of West Union, West Virginia, intended to replace the crank in steam engines and other machinery where the crank is now used. On the end of the shaft, to the place normally occupied by the crank, there is a heart cam, across the face of which, and at right angles with the shaft, a bar slides in suitable guides. The bar carries a lever, whose pivot is parallel to the main shaft and in the same horizontal plane. This lever has at each end a friction roller which rolls on the periphery of the heart cam, and from one side of the lever projects an arm which is connected by a rod, with a pin working in a slot in the bar already mentioned. A slide on the bar is provided with two pins projecting downward on opposite sides of the pin connected with the rod. The slide is connected with a hand lever, by which it may be moved lengthwise on the bar. The bar is connected with the piston rod of a steam cylinder or any other prime motor either directly or by means of a lever. The bar being reciprocated exerts a pressure on the periphery of the cam through the medium of the lever and its rollers. One end of the lever is below the center line of the bar, while the other end is above. This arrangement insures the rotation of the cam in one direction, and to reverse the motion of the cam all that is required is to reverse the position of the lever by moving the slide. The inventor claims that the cam has no dead points, that the power and motion are equal throughout the stroke, and that for this reason a fly-wheel is unnecessary. He also states that he gains a great deal of power over the crank, that it will run either very slowly or with any desired velocity, that it is capable of withstanding jars or shocks it is likely to receive, and is not liable to get out of repair. Further information in relation to the invention may be had by addressing the inventor as above.

Slipping of Locomotive Driving-Wheels.

Some very careful experiments have recently been made on the Northern railway of France to determine the slipping by locomotive driving-wheels at speeds varying from 43 to 74 miles per hour. The first experiments were made with a four-coupled engine having coupled wheels 7 ft. in diameter, and carrying a total load of 27 tons. It was found that this engine, when running light and in fine weather, at the high speed of 74½ miles an hour down a gradient of 1 in 200, apparently slipped continuously to the extent of 19%, while other engines also gave results of a similar kind, the slipping at maximum speeds apparently varying from 13% to 25%. Other and more recent experiments, however, show a different result at

speeds varying from 43 to 56 miles per hour. For this purpose six locomotives of three different types were used, five of them having four-coupled wheels, while the sixth was a Crampton engine, with a single pair of drivers. The circumference of the wheels was obtained by measuring the rails traversed by one revolution. The results showed that under the conditions of the trial no slipping whatever occurred, and that any doubts in regard to the partial slipping of driving-wheels under the ordinary conditions of locomotive working, may be set at rest, and that this supposed action need not be taken into account as a cause of wear and tear.

Singular Break in a Shaft.

The main shaft of the New York Steam-Power Company recently gave out under rather peculiar circumstances. The shaft was about 16 ft. long and 6 inches in diameter, and the fracture occurred within one of the boxes. When the shaft failed to do its duty it was discovered that the area of this final fracture was not over a half inch square, while the surfaces of the remainder of the fracture were black and greasy, showing that the break, with the exception noted, was an old one. The break extended diagonally across the shaft, and being jagged and irregular, the compression of the box and the small portion remaining unbroken had, for a considerable time, been sufficient to hold the shaft together. Why the force which produced the original fracture did not complete its work and destroy the shaft at the time, and why the shaft was afterwards able to run by the mere pressure of the box holding the two broken pieces together, are questions which have been exciting the attention of the thinking mechanics of the neighborhood for several days. From small pieces of the broken shaft which we clipped off evident signs of granulation in the iron were discovered.—*Blacksmith and Wheelwright.*

NOTES ON STEEL.—Steel merely hardened is hardest on the surface, while in steel that has been tempered the exterior is the softest. In the one case because the surface was cooled in advance, in the other because it was heated in advance. Steel which has rusted can be cleaned by brushing with a paste composed of one-half ounce cyanide of potassium, one-half ounce castile soap, one ounce whiting, and water sufficient to form a paste. The steel should first be washed with a solution of one-half ounce cyanide of potassium in two ounces of water. As the cyanide of potassium is a very dangerous poison, and as its fumes, when inhaled in sufficient quantities, will produce death, it should be handled with great care, and kept in a tightly corked bottle.

STEEL JOISTS are being made at a few factories in England and on the continent, but certain difficulties attend the rolling, which as yet prevents their manufacture on a large scale. Steel plates for bridges also are not as yet used to the extent anticipated, and the long span bridges in which their utility is undoubted, do not often occur. For boiler plates the considerable advantages which steel offers are being availed of, and for flanging and other treatment, where high quality Yorkshire iron was formerly used exclusively, steel is, says Messrs. Matheson and Grant in their half-yearly engineering trades report, found to be considerably cheaper, especially for plates of large dimensions.—*The Engineer.*

RETROGRESSIVE INVENTION.—It is reported that an American inventor proposes to apply dynamo-electricity to the working of a stone-breaker, with which he makes from 1,000 to 2,000 blows per minute, the actual breaking being effected with a wedge-shaped hammer. As to the actual crushing arrangement, it may possess certain advantages; but to use the power at second-hand instead of direct is retrogressive. Ten-horse power indicated at the steam-engine will give scarcely six-horse power after passing through a dynamo machine—that is to say, the alleged improvement would reduce the work done at a given cost to just over one-half.

METALLIC SHINGLES.—It is specially important that blacksmiths and carriage builders should have fire-proof roofs. A firm in New York manufacture a patent metallic shingle, which possesses so many advantages that no one in want of a good roof should fail to investigate its merits. They are much lighter than slate (weighing but one-fourth as much). Being laid in courses—each shingle by itself—no harm can result from the expansion or contraction of the metal, as is the case with tin roofs. Unlike wood shingles, they cannot warp or shrink. They make a more ornamental roof even than slate, as they can be painted to suit the taste. Many prominent buildings in different parts of the country have been covered with these shingles.

A COAL ECONOMIZER.—A company is being started in New York for introducing an article called the Coal Economizer, by the use of which it is claimed a saving of 20% in coal can be made. The economizer is in the form of a black powder, and is used by dissolving it in water and sprinkling the liquid over the coal in the bin. The theory of its operation is, that, through a chemical action, the gas which usually escapes in combustion is retained and utilized.

SCIENTIFIC PROGRESS.

Changes in the Earth's Figure.

An interesting hypothesis has been promulgated before the French Academy by M. Faye. It has been long known from geodetic surveys and pendulum experiments that continents and mountain ranges do not exert that attraction on the pendulum which might be expected of them; judging from the observed attraction of such isolated masses as Mount Schellhorn in Scotland, or the great pyramid. In fact the deficiency of mountains in this respect is so striking that in order to account for it, geologists and astronomers have imagined that there are vast cavities underlying continents and mountain chains. A somewhat different explanation of the feeble action of the Himalayas on the pendulum has been offered by Sir George B. Airy, who supposes that the attraction of the mountains is counteracted by still fluid lakes of rock below them. But this suggestion does not meet the fact, elicited by M. Saigey, that the attractions on islands of the sea is greater than it ought to be. It appears to be clear, however, that there is a relative lack of matter under continents, and an excess of it under oceans. The hypothesis of M. Faye would seem to solve the problem in a very simple and reasonable manner. He holds that under the sea the earth's crust has cooled much more quickly than under dry land, and hence the solid seabed is denser and thicker than the subcontinental mass. Water is a good conductor of heat as compared with rock, and being liquid it is also able to convey heat from its underlying basin. Geodesy shows that the present figure of the earth is an ellipsoid of revolution; but if M. Faye's hypothesis is correct it has not always been so. At first it was an ellipsoid, but the unequal cooling of the earth due to the liquid mantle covering it, led to unequal stress and the elevation of continents where the crust was thinner. These continents, according to M. Faye, surrounded the north pole, and the level of the ocean over our hemisphere was raised, thus bringing the earth to a more spheroidal form. Finally, as the cooling continued, the austral continents attracted the oceans and the figure became once more ellipsoidal, as it is to-day. If this ingenious speculation were the true one, it would unquestionably help geologists to explain the origin of glacial periods.—*Engineering.*

THE HEIGHT OF THE ATMOSPHERE.—HERT Ritter has published recent calculations on the height of the atmosphere, approaching the subject in a manner different from that of earlier investigators. His principle is this: The quantity of heat which must be communicated to a mass of air cooled to absolute zero to bring it, under constant pressure equal to the atmosphere, to the state of the lowest layer of the atmosphere, is the calorific equivalent of the mechanical work which would have to be expended to lift this same mass of air from the earth's surface to the limits of the atmosphere. Supposing, first, our atmosphere to consist of a gas which would retain the properties of a perfect gas to absolute zero, he gets the height 15.53 miles. Then, making the same calculation for an atmosphere of pure water vapor, he gets 217.43 miles. Considering, lastly, that while it is not possible to make an exact calculation for real gases, which certainly condense and solidify like water vapor before reaching absolute zero, one must obtain a result a little different from that found in the case of such vapor, he concludes that the height of our atmosphere must differ a little from 217.5 miles—a number which agrees well with that deduced by Schiaparelli from the observation of falling stars.

NEW POLARIZING PRISM.—M. Crova commends, for photometric purposes, in the *Journal de Physique*, M. Prazmowski's polarizer, which is a Nicol, with faces normal to the axis of a prism, the two halves of which are joined with linseed oil. It requires large pieces of spar, and the joining is long and difficult, but there are several advantages. Thus the layer of oil (unlike Canada balsam) cures hardly any loss of light; its index, 1.485, being nearly equal to the extraordinary index of spar, the polarized field is limited on one side, as in Nicol's, where the total reflection of the ordinary ray commences, by a red band; but the second limit, corresponding to total reflection of the extraordinary ray, is thrown out of the field of vision; the angular value of the polarized field is thus increased. The increase of field, the angular separation of the only colored band, and the direction of its bases, normal to the axis, are qualities to be appreciated in certain cases.

TOBACCO SMOKE PRODUCTS.—MM. Le Bon and Noel presented, the other day, in the French Academy, three flasks containing the following products extracted from tobacco smoke: 1, Prussic acid; 2, an alkaloid of agreeable odor, but dangerous to breathe and as poisonous as nicotine; 3, aromatic principles still undetermined, but contributing, with the alkaloid mentioned, to give tobacco smoke its perfume. The alkaloid in question is thought to be identical with a compound—collidine—the existence of which has been observed in distillation of various organic substances, but whose physiological and toxic properties have been overlooked.

Microscopical Examination of Ice.

Mr. M. A. Veeder has communicated to the *American Naturalist* some interesting results derived from recent microscopical examinations of ice which had been taken from pools of stagnant water in canals and ponds. The specimens were all taken from the interior of large blocks. This ice was found to be much more impure than even such ice is generally supposed to be. The small effect upon the fertility of germs is particularly noticeable. Mr. Veeder says:

On melting those fragments, and examining the water thus obtained with various magnifying powers up to 900 diameters, bits of vegetable tissues and coniferoid growths are usually recognizable at once. I have not noticed animalcules in an active state in water from ice that has just been melted; but, upon allowing such water to settle and become warm at the ordinary temperature of a room occupied for living purposes, the sediment deposited may be found to contain, after some hours, monads whose movements are easily discernible with a magnifying power of from 200 to 400 diameters. Upon allowing this water to stand still longer, I have found the coniferæ growing thickly, and, in some instances, forming clusters or bundles frequented by minute animalcules, the entire appearance in this case being similar to that presented by the nests occupied by the young of the common *Paramecium* which I have seen in stagnant water. As the result of these investigations I am fully convinced that freezing does not free water from filth due to the presence of sewage or decaying vegetable matter; and further, that it is altogether probable that the germs from which animalcules are developed, if not the animalcules themselves in a quiescent state, are present in very much of the ice taken from stagnant water. This being the case, it would seem that the use of such ice in drinking water is hazardous, to say the least.

ARTIFICIAL CITRIC ACID.—Among the latest triumphs of the synthetical chemist we have to record the preparation of citric acid by Messrs. Grimaux and Adam, of France. All the principal acids found in the vegetable kingdom had already been prepared, and for several years citric acid, the acid of the lemon, the currant and gooseberry, has been the only one of which it could be said, "this acid has not yet been made artificially." Tartaric acid has been made several years ago from dibromosuccinic acid, and malic acid, the acid of unripe apples, from monobromosuccinic acid, an acid obtained from amber; but succinic acid itself was made from ethylene cyanide.

LAWS REGULATING THE SPHEROIDAL STATE OF MATTER.—P. H. Boutigny states that the temperature of bodies in the spheroidal condition is always below that of ebullition; for water it is 97° (206°-6° F.). The spheroidal matter is never in thermal equilibrium with the vessel which contains it, but the vapor which escapes from it is always of the same temperature as the vessel. The spheroidal matter reflects radiant heat. The volumes of matter in a spheroidal condition are in a ratio inverse to their densities, and their masses are uniform. Some of the phenomena seem to indicate a repulsive force acting at sensible distances before vapor can be disengaged.—*Comptes Rendus.*

A NOVEL APPLICATION OF CELLULOSE.—A French sculptor, M. Emile Jeannin, has found a novel and what promises to be quite a useful and important application of celluloid. Noting that celluloid becomes plastic at a temperature of 250° Fahr., he tried whether it would be a fit substitute for the electrotypes used for illustrations. He found that it makes sharp and clear impressions, and that it resists the wear of the press-work much better than the ordinary cuts, having printed 56,000 copies from a celluloid cut without visibly injuring it.

INFLUENCE OF WINDS ON THE BAROMETER.—When a balloon is borne along by a rapid current calculations of its altitude are not trustworthy. When the velocity is very great, the error may be as great as one-third of the estimated height. Kaemtz, from the study of barometric observations at Paris, Zurich, Berlin and Halle, found that the readings were effected by the direction of the wind. Montigny has discovered a similar influence at other stations, but at Brussels and Namur the influence is directly opposite to that at Antwerp.—*Les Mondes.*

EARTHEN FILTERING PLATES.—G. W. Reye & Sons, of Hamburg, make filtering plates from a mixture of one part of gypsum with three parts of imperial earth in water. They can be purified after using by washing or burning. When impregnated with carbolic acid they also become useful as disinfectants.

ACCORDING TO M. Ader, any mechanical action that disturbs the molecular condition of a magnet core develops, when the core suddenly regains equilibrium, in electric current capable of affecting the telephone.

IN AID OF SCIENCE.—The French government has granted to M. Pasteur the sum of 50,000 francs for the purpose of enabling him to carry out his researches on the contagious diseases of animals.

AERIAL PHOTOGRAPHS.—By placing a camera in an aperture in the bottom of the car of a balloon very successful negatives have been recently obtained in Paris of the landscape below.

making its appearance again, and is looking very well, what there is to be seen. I will crosscut east and west immediately, and determine the size of the ledge on either side of the drift now run.

NORTH NOODAY.—The upraise being made from the 312 to the 412 levels is now 75 ft above the 312 level, and shows a large body of good milling ore. The 500 south drift is now 236 ft south of the crosscut; of this 18 ft was run during last week. The drift is in a large body of quartz.

PLACER.—The ledge continues strong and well defined, with the ore on the foot and hanging walls of excellent quality. There has been considerable increase in the amount of water coming from the ledge, but not enough to interfere with the work.

NOODAY.—The 212 south stopes have widened somewhat, both in the north and south end of the stope during the past week. The No. 2 north stope, 312 level, looks well. The south drift, 312 level, has been advanced 15 ft during the week; total length of drift, 750 ft. The stope on this vein is looking well.

BEVERLY.—There is no particular change to report in the different levels and stopes above and including the 650, and usual amount of ore (40 tons per day) is extracted and sent to the Syndicate mill.

COBENHAW.—They are drilling south at this mine along side the ledge, and taking out some good ore. In a few days it is proposed to crosscut the ledge, when the Goodwin may attract more attention than at any time in its history.

PLACER MINING.—Standard News, Aug. 29: But little placer mining is now being done on the eastern slope of Jodie ridge or on the flat beyond, but nearly all the ground in that locality has been located, and when the ledge is deep shaft down and its new and heavy pumping machinery in operation, and the Bodie-Mono shaft reaches the water level, and the Dudley pits in heavy pumping machinery, when all three of the mines named begin to pour heavy streams of water down over the rich placers of the eastern slope, there is no doubt but large quantities of gold will be extracted from the placer fields of Bodie—say early next spring.

LARK DISTRICT.—Mammoth City Herald, Aug. 21: The tunnels of the Mammoth are looking better now than at any period in the history of the workings of the mine. The true hanging wall has at last been found in the extreme south crosscut running easterly from No. 3 tunnel, at which point the ledge shows 20 ft in width with from 2 to 3 inches of clay selvage. The tunnel has been advanced 33 ft during the week, giving a total length of 1,293 ft. Tons of ore sent to the mill during the week, 461.

H. L. AND M. C. TUNNEL.—For the last 3 days the rock has been changing in character, growing coarse-grained and breaking handsomely. Distance run during the week, 23 ft; total length, 993 ft. This work may now fairly be said to be on the home-stretch, in good running ground.

LEWIS MINE.—Work has been suspended in this mine during the week, and all the force put to work on the adit to hasten its completion. Everything is now in place, the water turned on to the over-shot wheel, and the mechanics are engaged to-day in turning up the pulleys and making the connections. They expect to start up an regular business on Monday morning.

NEVADA.

ROCKY BAR MINE.—Nevada City Transcript, Aug. 27: A striking of 600 lbs of the rich ore recently found in the New Rocky Bar mine at Grass Valley was made Wednesday; 5423 ounces of amalgam was cleaned up from the battery and plates, and it is expected that there is enough more on the headings and pans to increase the amount to 600 ounces. H. L. Silvester owns about one-third of the mine. For 30 years he has been in business at Grass Valley, and invested a good share of his earnings in prospecting. This is said to be the first strike he ever made.

SAVING THE SILVER.—The Pioneer reduction works, under the supervision of Prof. H. C. and H. B. and H. C. and H. B. are being run to its full capacity on sulphurets from the Murchie and Morrill mines. A day or two since we saw a magnificent bar of silver which was the result of the working of the Murchie sulphurets. Our mining men are looking out for silver as well as gold, and find it quite profitable in saving the former.

ROUND MOUNTAIN MINE.—The entire force of employees at Round Mountain drift mine is busily engaged in breaking out about 75 carloads of good looking gravel per day. The last clean-up, made on the 1st inst., was satisfactory, considering the amount of dirt washed. Another clean-up will take place about October 1st.

NOTE.—About 75 ft east of the incline on the 120 level of the Mohican mine a 16-inch chute of rock that is heavy in sulphurets and shows some free gold has been developed.

MINES ON BEAR RIVER.—Grass Valley Union, Aug. 25: A company of Chinese is working the bed of Bear river just below the junction of Greenhorn creek with that stream. The stream has been turned over to the Nevada county shore and a large area of ground enclosed by an subankment, within which the pits are dug through the deposit down toward bed-rock and the pumps placed therein to pump out the water. The river bed is filled with deposits from the hydraulic washings to the depth of more than 20 ft, which necessitates the removal of a great deal of top dirt, which has to be wheeled out in barrows. There should be good pay at the bottom to pay for the large amount of dead-work required.

ROCKY BAR BONANZA.—Grass Valley Union, Aug. 25: The rich vein struck in the Rocky Bar mine last week shows no signs of giving out, although no pieces of extraordinary richness have been brought to the surface during the present week. The drifting has been going on. The ledge in the drift, however, shows well in iron ore. Besides more than \$5,000 worth that was crushed Wednesday, the company has yet on hand specimens to the value of \$3,000. All of this rock was taken out of the mine in 3 days, out of a space not exceeding 10 ft in length by 6 in width. The rich ledge is found 135 ft from the surface. Besides the strike in the west end of the Rocky Bar Co. have further to offer congratulation in finding a great improvement in the ledge at the bottom of the main incline (the Chavanne shaft) 450 ft deep, where the ledge in the drift shows from 24 to 30 inches, carrying well in sulphurets and yielding an average of \$30 per load. This good rock has been recently struck, and is the best rock yet found in the deep workings of the mine.

NEVADA CITY MINE.—Transcript, Aug. 23: All the stamps of this property have been running day and night since the latter part of July, when the number was increased from 5 to 10, and the average amount crushed daily is 18 tons. Stopping is going on in the 150 and 200 levels, the size and character of the ledge showing no material change since our last report. It is the intention of the management to begin next month to sink for a third level, the shaft not having been advanced any this summer.

SNEATH & CLAY MINE.—The Onida Old M. Co.'s agent here has received instructions to begin work on the Sneath & Clay mine about September 1st. It is to be hoped that the instructions will not be countermanded, as we have used to be considered a bonanza.

BEVERLY MINE.—Portland Tidings, Aug. 23: This mine has this week developed a 4-ft ledge of good looking quartz. The company intend thoroughly prospecting the mine and if this rock continues extensive operations may be looked for there.

YUBA MINE.—Reports coming down from Washington this week are to the effect that the Yuba quartz mine is looking well, and very well in fact, and the outlook for a permanently prosperous mine most promising.

NOTE.—Hydraulic mining all through the range from Dutch Flat up, and through this county, is having a longer water season than usual and paying well. The water bids fair to hold out until well along in September and some places later.

CONQUEST HILL.—North San Juan Times, Aug. 28: The shaft the Euro-Lako ditto company is sinking at the old town of Columbia Hill, is now down, as we are informed, 90 ft. The shaft is a very large one, 14 ft in length. It has 3 compartments, separated by strong and durable timbers. The process of sinking is naturally very slow. Blue gravel was struck at the depth of 60 ft, and

good paying gravel has been found from top to bottom of shaft. How much deeper the shaft will have to be sunk to reach bedrock can only be conjectured. The top of the shaft is from 150 to 200 ft lower than the original surface.

MADISON LAKE.—Grass Valley Union, Aug. 24: The Mohawk mine, in this district, continues to prospect well. We received a letter yesterday morning from Supt. Byrnes, in which he gives the most glowing accounts of it, and says it is bound to be a veritable bonanza.

PLACER.

LOWELL AND LIBERTY HILL NOTES.—Dutch Flat Forum, Aug. 25: We learn that the Planet mine has a tunnel in lora distance of more than 2,000 ft. The company will run a distance of 600 ft further when another incline will be made. The developments so far prove very evidently that a rich bed of gravel will be cut through in running the incline. Sound tests having gravel has already been found recently.

SWAMP ANGLE.—A large force of men is working this property. They also have 3 shifts of men on the new shaft, which is now down to a depth of about 75 ft. So far as can be ascertained by former prospects a good quantity of gravel will be opened up by this shaft.

DARBY MINE.—In this mine 10 men are being worked at the present time. The main tunnel is being run ahead, and there have every reason to believe good paying gravel will be struck at a distance of 300 ft, the distance decided upon to run in. This tunnel is being run in the bedrock close to the junction of the bedrock and gravel.

LITTLE YORK CO.—This company will shut down work for this season in their mine at Liberty Hill in about 10 days or 2 weeks, the water having run down to such an extent as not to be enough to work with. This company has had a good season's run and have taken out a great deal of gold.

GOLD RUN.—Cor. Auburn Herald, Aug. 28: Several claims, here and at the Flat, are still running with fair returns. The cement mill will soon be completed, when a revolution may be expected in mining affairs. At the quartz ledge half a mile below Old Run the owners are engaged putting up an adit for the purpose of thoroughly testing the rock.

DIAMOND MINE.—This property, situated 2 miles below Old Run, is being thoroughly prospected, an incline having been sunk to a depth of some 30 ft directly on the ledge. This ledge is looking well and shows good all through it. The ledge is 5 ft wide with streaks of red clay running through and parallel with the ledge. Gold can be obtained from every pan of this clay.

SHASTA.

IRON MOUNTAIN.—Bedding Independent, Aug. 26: The prospects of this district are improving. Senator Jones has put up \$1,000 to prosecute work on the Jones & Vanouy mine, and the latter gentleman, with Mr. Dervin, will commence work immediately. The location is considered by some to be the best on the mountain.

NOTE.—The tunnel on the Camden & Magee mine is being pushed ahead. They have struck soft rock and mud, and it is said the mud is stained with silver and will assay \$11 to the ton.

FREXET GULCH.—On the Scorpius mine they have struck water, and it will be necessary to build a bulkhead and run a drift to draw it off. It is reported that they have plenty of good ore in sight. A number of miners are employed and more are wanted.

SIERRA.

POVERTY HILL.—Downville Mountain Messenger, Aug. 28: From this property the owners divided a generous dividend this season. The rock mined in the handsome sum of \$45,000 last year. The ground enough left for an indefinite period. Their new tunnel is in 2,700 ft, and will reach the channel in about a year more, if not sooner.

HOG CANYON.—Parties are engaged in running a tunnel in Hog Canyon to strike the old Primrose ledge. The tunnel is started just back of the shaft house, and runs into the hill. It is now in some 40 ft, and is being vigorously pushed ahead.

COLD BLUFF.—We are informed that the Cold Bluff mine is being fitted up, and will be started in the near future. A great deal of work has been done to develop the mine during the past year. This property paid well for many years, until the upper levels were exhausted.

BRANDY CREEK.—This property, the Fairplay company has had a satisfactory clean-up. The Cleveland has done as well. Union Hill had a short water season, but realized large returns.

CORNCUT HILL.—The Celestials at this mining center are hydraulicking down a plentiful supply of nuggets and coarse gold.

RED YIELD.—Arnott & Baird's hydraulic claims, at Brandy Creek, have this season paid the lucky owners the handsome dividend of \$14,000.

NOTES.—The Virginia mine, at Howland Flat, was bonded last Tuesday to San Francisco capitalists for \$150,000. At Plum Valley, Nelson & Co. are making extensive preparations to run the Tippecanoe next season.

TUOLUMNE.

THE OLSEN LOBE.—Sonora Independent, Aug. 23: The company that is working the Olson mine, at Golden City, has traced the vein westward to a point 4 miles north-easterly from Knight's Ferry, a distance of 10 or 12 miles, where it has a force employed prospecting, and the results are most satisfactory. A number of tons of ore from the shaft have been tested, and have very promising returns. The ore is, in character, much the same as that at Golden City, which leads the company to believe it to be one and the same vein, considering its course and character. Thus may it naturally be inferred that there exists niles in extent of this mammoth quartz lode, upon which no claims have yet been located.

NOTE.—The vein is 1 mile or thereabouts, from the locality named, on lands owned by Samuel Dingley, and only a few rods from his dwelling house, the continuation of the vein is to be plainly seen in a trench some 3 ft in depth, washed out by the winter rains. Mr. Dingley, we understand, has already located and contemplates sinking a prospect shaft on the vein at some favorable point not yet determined upon definitely.

TRINITY.

NEW RIVER.—Weaverly Journal, Aug. 23: We learn that the New River hydraulic mining company has contracted for the building of the 9 miles of ditch and flume required to bring their water on to Hawkins' bar, for the sum of \$63,000. There will be about 5 miles of fluming on the route, and everything considered, the company has succeeded in letting the contract at a low figure. The work will make lively times in that section while it lasts.

NEVADA.

WASHOE DISTRICT.

SIERRA NEVADA.—Cold Hill News, Sept. 1: The mining situation has, in some respects, changed at the north end, where developments are soonest expected. Sierra Nevada is following ore south from crosscut No. 2, 2300 level, to crosscut No. 1, where 0 ft of ore were found. The north drift, 2500 level, is getting promising quartz already.

UNION.—Union is working hard, but has not yet reached the point where the chockholders believe it has grasped the mainline, winze No. 1 is sinking through low-grade ore for the 2000 level, and the shaft, when some law things are finished, will be sunk to that level also, and then the 2 workings will be connected.

ORION.—The heavy vein material which has been so promising in Ophir has been lost sight of late, but it is there all the same, and a drift on the 2500 level is following the trend of the vein. The work will carry the vein should that trend hold, fully 900 ft east of the Union shaft, and doubtless when time permits and opportunity presents a drift will be run in that direction in search of it.

BELOCHER.—The necessity which exists for Belcher's suspension of operations on the 3000 level just at this time, when the best level of connection on the 3000 level with Crown Point and necessary ventilation have been secured, is a little discouraging; but the delay of a month will quickly pass, and then the mine will be in condition to make up for lost time.

AURORA DISTRICT.

REAL DEL MONTE.—Esmeralda Herald, Aug. 21: Owing to the accident but little work was done in the mine the first of the week. Wednesday the new clack-chamber arrived and was put in place immediately. Thursday morning sinking was resumed. Everything is now working as smoothly as though nothing had ever happened.

THE PROSPECTS.—The Blasted tunnel is now about 230 ft in length and the work still going straight ahead. The face is still in blue porphyry. If some of the mine owners that are working tunnels over 200 ft in length with wheelbarrows would go and observe the manner in which the car comes out of the Blasted tunnel, we think they would discard the wheelbarrows and get cars.

GRAND TRUNK.—A new drift was started from the crosscut south and driven 20 ft, following a streak of yellowish looking ore that gives a very good prospect.

THE QUINCY.—Sinking on the ledge and taking out ore still continues. A depth of about 20 ft has been reached, and there is some 5 or 6 tons of ore on the dump. The ore was excellent on the very surface, and has been improving all the way down.

CENTENNIAL.—The working force has been increased, and the work of taking out ore progresses more rapidly. As soon as the little mill starts up, which will be probably the middle of next month, they will make a crushing.

MCLINTOSH & DARNES.—Messrs. McKinlay & Winters have cut between 4 and 5 tons of fine ore. There are 2 very rich streaks in the ledge, and the ore on the dump is taken from these streaks. A crushing will be made as soon as the mill starts.

BRISTOL DISTRICT.

DUNSTON CO.—Pioche Record, Aug. 21: The machinery of this company has been located, and everything worked like a charm. Arrangements for putting up a tank with a capacity for holding 60,000 gallons will be completed in a short time. The company has already put on teams hauling ore.

NOTE.—The Hillside company now employs 75 men at the mines and furnace.

COLUMBUS DISTRICT.

NORTHERN BELLE.—True River, Aug. 21: The lora-tion is still very hard. About midway of the 3d level, a crosscut was started in which some very fine ore has been found. The 1st and 3d levels look full as well as last week. There is no change in the levels above the adit. About 35 tons of ore shipped per day to Belleville, where the company's mills are situated. The bullion shipped up to Aug. 15th is \$76,973.71. Both mills and mine are running satisfactorily.

MOUST POTOMI.—At present 12 tons of ore per day are being taken from the mine. The No. 2 tunnel is being pushed ahead as fast as possible, with seams of ore all through the base of the drift. The No. 1 tunnel is being cast central drift in No. 2 tunnel was started with good ore in the face. This drift will open up their back ledge and cut it at a depth of 140 ft. The company has taken 75 tons of good ore from the croppers of this ledge, and expect to develop a good body of ore as soon as the ledge is cut.

VICTOR.—The company is shipping 23 tons of first-class ore per day to New Boston. The ore comes from the bottom of the incline 140 ft deep. The mill at New Boston will be started up on this ore in a few days.

BELENO.—A crosscut has been started south from the bottom of the incline, at a depth of 210 ft, to cut the ledge from wall to wall; the crosscut is in now 8 ft, and all ledge material.

EQUATOR & METALIC.—The shaft at the present time is down 350 ft, a distance of 65 ft having been sunk this week; the bottom of the shaft is in ledge material.

WINSTON.—The shaft has reached a depth of 140 ft and still in ore.

EUREKA DISTRICT.

RICHMOND COX.—London Mining Journal, Aug. 7: The manager reports that operations have been carried on with usual regularity. No. 14 chamber has considerably improved since last report. In the southwestern end a winze has been sunk in good ore to a depth of 30 ft, and promises to open to a good ore body. No. 15 is without any material change.

NOTE.—An important strike of ore is reported in the 500 level in a drift running parallel to the old workings in Dunderberg and Atlas ground. This drift is in entirely unbroken ground, and adjoins the immenso chambers of ore from which the parties previously in possession of the property obtained about \$750,000 net profit.

PROSPECT MOUNTAIN TUNNEL.—Sentinel, Aug. 23: Reports from this great enterprise are most flattering. The rate of the shaft is now in favorable ground for the existence of ore bodies.

GRANTSVILLE DISTRICT.

ALEXANDER MINE.—Belmont Courier, Aug. 21: This is one of the biggest mines in the State. The mountain seems to be nothing but ore. A ledge measuring over 450 ft in width, and prospected to a depth of 600 ft, is surely a bonanza for any camp. In all the levels the ore is of the same extent and character, and the indications are favorable for its going down to a great depth.

BRADLYN.—Hoisting works are going up on this mine. It promises to open finely, and the ore is of a high grade.

LUNDY DISTRICT.

MAY LUNDY M. CO.—Esmeralda Herald, Aug. 21: We learn from Mr. Z. B. Ravenel, who has just returned from this district, that he has contracted with the May Lundy mining company for the transportation of their ore from the mine to their proposed mill site. The mine is about 3 miles from the place selected to build the mill, which is to be erected immediately, and will be of a 10-stamp capacity. Mr. Ravenel describes the ore as being so very rich that you may take up a piece at random and find free gold. In fact, he says that it is the exception to pick up a piece that has not free gold in sight.

OSCEOLA DISTRICT.

OLD CHANNEL CO.—Cor. Ward Repter, Aug. 19: We are down 65 ft. Have passed through 45 ft of concrete or cement, and have come to what was known in California back channels as pipe clay. The clay is red and full of wash boulders. We get some small prospects of wash gold. Expect to sink at least 50 ft more before reaching bedrock. All are hopeful, and it is the general impression that something substantial will be struck.

PHILADELPHIA DISTRICT.

ELMONT.—Official Letter, Aug. 17: There is no material change in the mine. Ore stopes continue looking very favorable. Extracting about 10 tons of first-class ore per week, and 25 tons second-class ore per week. Air winze to north stope is completed, which gives good air in the stopes above 300 level. Have commenced getting rock and brick on the ground to put up the boiler for the concentration mill.

PIOCHE DISTRICT.

RAYMOND & ELY.—Record, Aug. 21: The personal property of this company was sold at Sheriff's sale last Saturday, and was bid in by the mortgagees. They are now in the state of liquidating the Raymond & Ely and Meadow Valley companies down at San Francisco, but are unable to come to an agreement.

DAY MINE.—Work in this mine progresses steadily and developments continue very favorable. Ore has been encountered in the drift run from the 400 level, the deepest workings in the mine, assays from which going as high as \$500.

REBEL CREEK DISTRICT.

QUARTZ DISCOVERY.—Winnemucca Silver State, Aug. 25: Another recent mining discovery in this district, 3 miles north of the Ohio mine, is attracting considerable attention. The new ledge is called the Iowa, and the locators have sunk a shaft to a depth of 25 ft on the ledge. The vein is between 7 and 8 ft thick, and the average assays of several pieces of the ore is \$274.37 in silver, and \$12.55 in gold to the ton. The highest assay obtained was \$2,000 to the ton.

SPANISH BELT DISTRICT.

BARCELONA.—Official Letter, Aug. 18: Since my last report we have advanced 12 ft in north level through a

splendid ledge of high-grade ore, with walls perfect. Have been forced to turn all hands on upraise, so as to push it to completion as soon as possible. I am short of good miners and air very close. Have advanced 15 ft in upraise and hope to make connection soon.

SPRING VALLEY DISTRICT.

PLACER MINES.—Winnemucca Silver State, Aug. 26: We learn from Mr. Peter Spray, of this district, that the Eagle mill is shut down for nearly a year, and the work is suspended in the mine on account of the high water. He says that about 100 Chinese are working in the placer mines near the Eagle. They hoist water out of shafts on quartz mines to wash the gold-bearing gravel. Sometimes, in fact quite frequently, they make as high as \$100 a day to the hand in washing the gravel.

WHITE PINE DISTRICT.

TRENCH MINE.—News, Aug. 25: We learn from this Superintendent that the recent strike in the Trench was made in shaft No. 2, 30 ft below the surface. The shaft has been sunk 5 ft lower, and the ore appears to be coming in strong. It is of the same character as the rich ore formerly taken from the Trench—black auriferous.

FEATHERSTONE.—An important strike has just been made in this mine, lying back of the town. The ore assays up in the hundreds.

BADGER STATE.—This mine, on White Pine mountain, has a shaft down 95 ft. They have a good body of ore, in which gold predominates.

WILLOW CREEK DISTRICT.

A RICH STRIKE.—Paradise Reporter, Aug. 21: We are pleased to record another rich strike at Willow Creek. The ledge has been struck in the Iowa Co. claim, and carries ore that assays from \$305 as high as \$3,300 in gold and silver. These are assays from the surface only, but the mine is being actively developed by 2 shifts of men and presents a very encouraging appearance. From the valuable mineral deposits that have been discovered in the vicinity of Willow Creek, it is safe to predict prosperous times for the district.

ARIZONA.

SILVER DISTRICT.—Cor. Phoenix Expositor, Aug. 18: We have had no rain for nearly a year, and the tanks at the Klara camp are the only ones containing water in the district. No scarcity at the mines, however, as they are abundantly supplied by teams and burro trains, from the river, 5 miles distant.

SILVER MINE.—The quarrying on the surface of this mine continues, the ore becoming richer as they enter the mountain. This is the only silver quarry now being worked, to my knowledge, in the mining world, and would repay a visit. Eight assays of ore taken at random from the dump yielded from \$112 to \$2,407 of silver per ton, and a per cent. of lead ranging from 24 to 78.

NOTES.—The Iron Cap is sinking away, and have opened on a handsome and heavy seam of metal on the foot wall. The Chicago Co. has 14 lodes in this camp. It will open up from the rain comes.

MILK MOUNTAINS.—Tombstone Nugget, Aug. 10: Encouraging reports continue to arrive from this district. Their enormous ledges are showing up better than ever in width and value per ton. Ben Johnson's claim, called the Lillie, shows a 25 or 30-ft vein, assaying about \$100 to the ton, while Foley & Egloff property is showing equally well. A recent blast in the Copper Queen works is said to have laid down a ledge, where it can be conveniently handled, hundreds of tons of ore, and leaving exposed such a body as had not been seen before.

CHARLESTON DISTRICT.—Among the mines which are assuming importance is the Lizzie, situated about 11 miles this side of Charleston. The developments consist of a shaft 55 ft deep showing a fine vein of extra high grade ore. From this shaft a long drift is to be run, following the ore body.

NOTE.—News from the Dragons give big finds and some of our citizens have gone out to get their fingers into the silver pit.

GLOBE DISTRICT.—Silver Belt, Aug. 21: The Independence mine, about 7 miles north of Globe City, exposes an ore body of 3 to 5 ft, with argente walls, in which silver can be seen in its native state. There has been a large amount of ore taken from this mine in the month of July, with satisfactory results, besides a lot milled, which gave a return of 290 ounces per ton.

STONEWALL MINE.—This mine is about 2 miles east of Globe City, and has a vein ranging from 0 to 25 ft wide, the ore averaging about 60 ounces per ton.

COX & CORLIN.—About 8 miles north of Globe, and near the Independence. At the surface the vein varies from 12 to 30 ft wide, but at a depth of 100 ft it shows the enormous width of 60 ft. The ore milled from this mine gave a yield of \$400 per ton, while assays made from the surface to the present depth of tunnel on main ledge, ranged from 100 ounces per ton to almost pure silver.

COLORADO.

CLARK CREEK COUNTRY.—Colorado Miner, Aug. 21: The lessees on the Colorado Central lode, who are drifting west from the bottom of engine shaft No. 2, have struck a very rich streak of ore composed of ruby silver and gray copper running up into the thousands. The pay streak will average 6 inches in width.

COST LOBE.—Another rich strike was made in this lode, on Brown mountain. The ore runs very high and carries a great deal of ruby silver and gray copper.

Snowdrift Co.—This company, which recently commenced work upon their property on Republican mountain, have struck a fine body of ore in the lowest drift upon the Daniel Peters lode, which assays between 700 and 800 ounces of silver per ton.

SNEVELY LOBE.—This lode, on Brown mountain, still continues to produce its full complement of ore. The last assay was as follows: First class, 475 ounces; second class, 450 ounces. Last month there were 13 tons of ore shipped from this mine.

SENKA LODE.—This lode, on Sherman mountain, is developing finely. The ore vein is continuous, and averages from 2 to 4 inches, which assays from 130 to 1,500 ounces, and mill runs: First class, 620 ounces, and the second class, 380 ounces.

RED BOTTLE LODE.—Georgetown Courier, Aug. 10: A rich strike has been made in this lode on Red Elephant mountain. They have from 12 to 18 inches of ore carrying carbonate of copper that assays from 2,000 to 2,500 ounces of silver per ton.

IDAHO.

LEMMU COUNTY.—Yankee Fork Herald, Aug. 21: The work of developing the Badger mine will be carried forward all winter. A tunnel is to be run to cut the ledge at a depth of 300 ft below the present workings. The mine is opened by a 90-ft shaft, from which a west level is extended a distance of 240 ft, all the way through good ore. The vein is 4 ft in width; the first-class ore samples over \$1,400 per ton; the second class, \$800 to \$700; and the third class about \$150.

CUSTOM MILL.—J. Sharon has his 10-stamp custom mill on the road between Challis and this place. He has purchased Matt. Bray's mill site, at the mouth of Jordan creek, a quarter of a mile above town. The pans and settlers have been ordered from Virginia City. It is the intention to have it running in 6 weeks.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department No. 10, San Francisco:

VULCAN CON. M. CO.—Location: Nevada. Capital, \$10,000,000. Directors—A. F. Benjamin, F. Sperling, Geo. T. Knox, T. D. Olmstead and M. E. Spang. He has purchased Matt. Bray's mill site, at the mouth of Jordan creek, a quarter of a mile above town. The pans and settlers have been ordered from Virginia City. It is the intention to have it running in 6 weeks.

POTOMAC M. CO.—Location: Nevada county, Cal. Capital, \$100,000,000. Directors—L. R.

The Inter-Oceanic Ship Railway.

[CONTINUED FROM PAGE 145.]

provements should be referred not to those who are merely skilled in the use of tools, but to those who understand and can analyze and demonstrate the principles involved; and those schemes that will not bear this scrutiny should be left alone.

We ask legal advice, not from the copyist in a law office, but from those familiar with Coke, Littleton, Blackstone and modern lights in the science of law. We seek medical treatment, not from the mere compounder of drugs, but from those whose course of study and knowledge of therapeutics show them to have been diligent students of medical lore. We send our watches for repairs to no blacksmith, however skillful. Do we trust our engineering to other than engineers. This is the California practice, with few exceptions. Physicians who would not treat an opulent patient for smallpox without a good round fee—lawyers who charge \$5,000 for conducting an important suit in court—Presidents of banks and other institutions receiving \$10,000 to \$20,000 per annum for their services, trust engineering enterprises upon which their fortunes are dependent to men willing to work for \$50 or \$100 per month rather than employ a respectable engineer who will not degrade his profession by working for nothing unless circumstances compel him to do so. These gentlemen see the force of our reasoning in their own cases, but usually learn only by dear-bought experience, its application to engineering. Now all this is so apparent when attention has once been called thereto, that we fear the public will be tempted to say, "We knew all this before." Then, will it permit us to inquire, why has it not governed itself accordingly?

Usually too cautious thus to expose itself, the unprogressive element to which we have referred occasionally ventures upon what bears the semblance of argument. Just now it is dilating in private circles upon the ruinous strains to which it asserts that ships would be subject on a railway.

This plea is so plausible on its face, and seems so reasonable to the unprofessional mind, that it makes no little impression, and is freely and very properly offered rather as a suggestion than otherwise, by many intelligent gentlemen who are by no means to be confounded with the unreasoning or unprogressive element of which we have been speaking. Hence it merits respectful consideration and courteous answer.

On the 31st day of December, 1870, a paper was communicated to the Royal Society giving the first exact and really scientific treatment that many of the problems relating to the strains upon ships had ever received, and clearly showing the errors of previous theories. Unable to recall where we had seen this paper, and not sure of the author, for the purpose of showing the foregoing objection to be unsound, we divided the hulls of several vessels of modern construction into transverse sections, represented by the vertical lines *v*, fig. 1, and calculated the weight of hull and equipment and the buoyancy of the divisions between these lines, which gave us the excess of weight or buoyancy of each division, and enabled us to compute the still-water strains upon any part of the hull of each ship so treated, and approximately the strains upon the crest of waves and in the trough of the sea. To illustrate our figures, we prepared several diagrams, in each of which the still-water load-line of the vessels are shown by the lines *c*, *c*, *c*, and the wave crests and hollows by the lines *o*, *o*, *o*; and to avoid the confusion of intermingling lines, we prepared separate diagrams for each of the latter. Since making these calculations, which were exceedingly tedious, we have found reprints of parts of this paper in Vols. 1, 2, 3, of *Naval Science*. It was written by E. J. Reed, C. B., Vice-President of the Institution of Naval Architects; Member of the Institutions of Civil Engineers, and of Mechanical Engineers; honorary member of the Liverpool Literary and Philosophical Society; author of "Ship-building in Iron and Steel," "Our Iron-clad Ships," editor of *Naval Science*, and late Chief Constructor of the navy, the authority quoted by Captain Eads, and justly termed by him "perhaps the first authority in the world upon all matters relating to ships." Retaining our own diagrams, slightly modified for the purpose, we substitute his ships and the strains given by him in lieu of our own, that the startling figures developed by these calculations may have the authority of his great name. Those interested in such matters are referred to his exhaustive article, for it contains much of interest foreign to the purpose of this paper, and we have space to handle only a few of his results and these in the briefest manner.

Let fig. 1 represent the royal yacht *Victoria and Albert*. This is given by Mr. Reed as a representative of the long, fine, fast paddle-steamers used for pleasure, for blockade-running, or passenger traffic, without much freight. Starting at the bow, where the weight is in excess, and proceeding aft, with gradually increasing buoyancy, we find 50 ft. from the bow a transverse section *a*¹, where the weight and buoyancy are equal. This is termed a water-bourn section. Continuing aft, with still increasing buoyancy, at a point about 68 ft. from *a*¹ we find another water-bourn section, *a*²; 82 feet further aft a third, *a*³; and 70 ft. further—30 ft. from the stern, the aftermost water-bourn section, *a*⁴.

The weight in front of the first water-bourn

section exceeds its buoyancy by 85 tons. Between *a*¹ and *a*² the buoyancy exceeds the weight by 225 tons; between *a*² and *a*³, where the boilers, engines and coal are situated, the weight exceeds the buoyancy 210 tons; between *a*³ and *a*⁴ the buoyancy exceeds the weight 130 tons, while aft of *a*⁴ the weight exceeds the buoyancy 60 tons. This distribution of weight and buoyancy we have graphically represented in fig. 2 by cutting out of the vessel those portions where the weight exceeds the buoyancy and suspending in lieu thereof, and at the center of gravity of these sections, the shaded squares representing the excesses of weight, the sum of which equals the sum of the excesses of buoyancy. These weights at the ends produce what are termed hogging strains, which, but for the sagging strain produced by the weight amidships, would find a single maximum hogging moment near the middle of the length. But, in consequence of this sagging strain, there are two maximum hogging moments, the first and greatest between *a*¹ and *a*², about 86 ft. from the bow, where it amounts to 5,080 foot-tons. The minor maximum hogging moment falls upon the buoyant section between *a*³ and *a*⁴, and is considerably lighter. About 30 ft. of the midship section is subject to a sagging moment, the maximum value of which is only about 170 foot-tons, though the excess of weight over buoyancy is 210 tons. A small change would convert this sagging into a hogging moment. Let 4 tons of this weight be moved 150 ft. to the front, and 6 tons carried 100 ft. aft, the hydrostatic equilibrium of the vessel is unchanged; but this change of weight would produce a hogging moment of 600 foot-tons, which, combined with the sagging moment of 170 foot-tons previously existing, would leave as a final result a hogging moment of 435 foot-tons at the point where the sagging moment of 170 foot-tons had previously existed. This shows how seriously a vessel may be strained by an improper disposition of the cargo. It shows, also, that an excess of weight amidships does not necessarily involve a sagging strain, for, after these changes, there would still remain an excess in weight of 200 tons. And again, it shows the necessity of taking into account all of the forces acting upon one side of the section for which the bending moment is being calculated; as, unless this is done, it is impossible to determine whether sagging will take place or not, for the hogging moment due to the unsupported weight at the extremities will often more than counterbalance the sagging due to excess of weight amidships, as well as the converse.

We will now suppose this vessel to be balanced upon the crest of a wave of its own length, 300 ft., and 20 ft. high, fig. 3. At the bow the excess of weight is now 220 tons, and at the stern 185 tons, while the former deficit of buoyancy amidships of 210 has become an excess of 405 tons. The hogging strain of 5,080 has now risen to 16,400 foot-tons, or more than three times that of still water, and its maximum moment has shifted from within less than 90 ft. from the bow to near the middle of the vessel.

When this vessel floats in the wave hollow, fig. 4, the strains brought to bear on her are very remarkable. The still water excess of 210 tons' weight amidships now reaches an excess of 785 tons. The excess of weight at the ends has changed to an excess of buoyancy of 390 forward and 395 tons aft. The result of this is to produce sagging moments throughout the entire length, increasing as we recede from the ends, and reaching its maximum near the middle, where it amounts to 31,000 foot-tons, more than six times the bending strain in still water.

Fig. 5 illustrates the disposition of weight and buoyancy on the wave crest, of the *Bellerophon*, "an ironclad of moderate length and proportion, with central batteries, armor belts and fall-back stern." The advantage of this bow in giving increased buoyancy is shown by the fact that the foremost water-bourn section *a*¹ is only 40 ft. from the bow, and the excess of weight on this length is only 45 tons in still water, though it amounts to 445 tons when the ship is balanced upon the crest of a wave of its own length and 20 ft. high. The aftermost water-bourn section is about 50 ft. from the stern, and the excess of weight on this section in still water is about 220 tons, reaching 555 tons upon the wave crest. This ship has a still water excess of weight amidships of 250 tons, and yet no sagging at any point. On the wave crest this 250 tons still water excess of weight became 1,000 tons excess of buoyancy, and the maximum hogging moment reaches 43,500 foot-tons, or 3½ times that of still water, and falls very near the middle of the ship, whereas in still water it falls considerably abaft the midship section.

The 1,000 tons excess of buoyancy amidships on the wave crest changes to 1,240 tons excess of weight in the hollow of the waves, Fig. 6, while the excess of 445 tons weight forward, and 555 aft, change, respectively, to no less than 640 and 600 tons excess of buoyancy. The maximum bending (sagging) moment is 48,800 foot-tons—about 4 times the maximum bending (hogging) moment in still water, and about 5,200 foot-tons greater than the maximum hogging moment on the crest of the wave.

The *Minotaur* is armored throughout its length, and is a fair representation of extremely long, fine ships so protected, with V-shaped, transverse, vertical sections at the bow. Her length is 400 ft. The heavy weights of engines, boilers, coal, water, powder and provisions are distributed over a considerable portion of its length; the guns are also distributed along the

broadside, and the weight of the hull is nearly uniform except at the extremities."

"In this ship there are only two water bourn sections, *a*¹ and *a*². The first is about 80 ft. from the stern, and before it the weight exceeds the buoyancy by about 420 tons. The second is about 70 ft. from the stern, and on this length there is an excess of weight of about 450 tons; between *a*¹ and *a*², a length of 250 ft., the buoyancy exceeds the weight by the sum of these excesses, 870 tons."

"This ship is subject to hogging moments at every transverse section, gradually increasing in amount from her extremities toward the middle of the length and obtaining their maximum value near the midship section (240 ft. from the bow), where it amounts to 45,000 foot-tons." At *a*¹ the hogging moment is about 19,000, and at *a*² 20,000 foot-tons. The bending moments due to the longitudinal pressure of water against the sides of this ship have a maximum value of 3,700 foot-tons. The maximum bending moment due to vertical bending force has been given as 45,000 foot-tons, or about 12 times as great.

On the crest of a wave 400 ft. long and 25 ft. high this ship has an excess of weight forward of 1,275, and aft of 1,365 tons; with an excess of buoyancy amidships of 2,640 tons; its maximum bending (hogging) moment in this position, Fig. 7, is 143,300 foot-tons, or about 8 tons per square inch of iron section.

In the wave hollow, Fig. 8, instead of 1,275 tons excess of weight forward and 1,365 tons aft, we have 655 and 695 tons respectively, excess of buoyancy, and, instead of 2,640 tons excess of buoyancy amidships, we have 1,380 tons excess of weight. This gives a maximum bending (sagging) moment of 74,800 foot-tons, or a little more than one-half the maximum hogging moment on the wave crest. The transit of waves 400 ft. long is 8.85-100 seconds. In one half this time we may suppose this ship to have passed from wave crest to wave hollow during which she has been wracked from stem to stern by these enormous and rapidly-changing strains, her maximum bending moment passing from 140,000 foot-tons hogging to 74,800 foot-tons sagging strain, and as her downward course is suddenly checked, as she settles in the trough of the sea, these strains are vastly increased. When we try to combine with these the strains exerted by the wind and sails and leverage of masts, by the rolling and pitching and tossing of the vessel and the mighty blows of ocean waves, the problem becomes too intricate for finite intelligence ever accurately to solve. But when we consider that the engineer is able approximately to calculate and to control these mighty forces—to build his ships to stand the storm, to drive them swiftly, safely, unerringly against wind and wave, through fogs and midnight darkness and the howling tempest, across vast oceans to their destined ports at the appointed time—we are proud for that grand profession whose triumphs are dotting the ocean and changing the face of the globe.

The weight of ships, until launched, rests almost entirely upon the keel. We learn from Mr. Reed that the iron ship *Prince of Wales*, when being launched, stopped and remained for some time with her bow resting upon the edge of a wharf, her stern being supported by the water. Though thus suspended by the extremities, no damage took place. The wooden line-of-battle ship *Cesar* stopped on the launching ways at Pembroke in 1853, and remained for 17 days with 64 ft. of the stern unsupported by ground ways. This caused a drooping of 2 ft. in 90. In 1866, the iron-clad frigate *Northumberland* stopped, when being launched, with 52 ft. of the after part unsupported, and remained so for 30 days. The weight of the unsupported part was about 450 tons, and the momentum of this weight at the point of support 11,700 tons. The result of this strain was a deflection of 7-16th of an inch in a length of 342 ft., which was reduced to 5-16th when the ship was floated.

It is obvious that in a strong cradle, supported by numerous wheels upon the smooth, even, rigid bed of a 12-rail roadway, no ship could be subject to any such strains as those we have been considering, and we dismiss this question without further comment.

A few words more and we bring this somewhat rambling paper to a close. We have by no means taken up the advocacy of the railway in opposition to the canal. We have been an interested advocate of the latter for years; have studied all the surveys and reports; carefully examined all the maps, charts, estimates and plans, and our preferences have always been largely in favor of the Nicaraguan route. But, in the few remarks made by Capt. Eads before the Chamber of Commerce, there is food for much reflection. The fact that he advocates the railway, should bid us pause. Engineers do not lightly hazard an opinion. Of all men, they are usually the most cautious. From want of efficient data, they sometimes doubt the success of schemes that are subsequently carried into successful operation, but in the things they do endorse there is little room for doubt, for they take nothing upon trust, but deal solely with facts and figures. Either of these schemes is of the greatest importance. Either in successful operation would be far reaching in its results, effecting for good or ill the commerce of the world—the welfare of our race. They merit, therefore, the best thoughts, not only of engineers, but of philanthropists, financiers and statesmen. Capt. Eads' views have been before the world long enough to have received careful consideration. It is not easy to see how his

conclusions can be avoided. If there are those who can successfully controvert them, they are strangely tardy in making it known. If any there are who can point out a serious objection, they have not yet spoken, while in a matter of such world-wide importance, silence on the part of such persons is almost a crime.

The writer has expressed himself somewhat freely in this paper, but having always the courage of his opinions, he seeks no shelter behind an editorial impersonality, and therefore subscribes himself,

A. B. BOWERS, Engineer.

From Vera Cruz to Mexico.

Starting from the sea shore and directing his course inland, the traveler finds, as he proceeds, that he is gradually rising through the different gradations of the torrid zone and entering upon temperate latitudes. This he can at once detect from the decreasing heat, and, more particularly, from the change in the style of vegetation which surrounds him. A run over the railroad from the Gulf port of Vera Cruz to the city of Mexico is a revelation to the intelligent stranger. This is the only completed line of railroad in the republic. The distance between the two points is about two hundred and sixty miles, the run being made in a little over eighteen hours. There is probably no road of equal length in the world upon which the traveler can pass so rapidly from torrid to temperate zone—from the region of the palm to that of the pine—and through so varying a panorama of wonder and beauty, as upon this Mexican road. Leaving the hot, fever-ridden sea coast at Vera Cruz, where death and the black vomit have maintained a reign of terror since the landing of the first Spaniard, your car rolls westward for a couple of hours over a level sand plain, covered with low, dense vegetation, interspersed here and there with giant trees, many of them leafless and apparently dead. The huzzard, or sopilote, as the natives call him, loves these solitudes, and countless numbers of them are forever perched along the naked limbs, or flapping curiously past your car window. From this low plain the road gradually emerges, the country begins to roll a little, the foothills draw near, the vegetation takes on another tinge and form, and before you can fully make up your mind to the change you are skirting the banks of a limpid stream, with picturesque hills on either side. The ascent is now rapid, and a charming panorama of mountain, stream and canyon, with occasional glimpses of the Gulf of Mexico in the distance is before you. Your car is headed bravely for the heart of the Cordillera, which rises blue and mysterious far above you; and now and then, as you twist and curve about the canyons, glimpses may be had from the car window of the white cone of Orizaba, which lifts its pale tip up so close to Heaven that the Indians call it the Mountain of the Star.—D. S. Richardson in *September Californian*.

FAILURE OF THE LIVADIA'S STEEL BOILERS.—Those engineers who hold that steel is not a good material of which to make boilers, will find support for their opinions in the failure of the boilers of the Czar's yacht *Livadia*. This vessel was to have had eight main boilers of steel. Six of these were finished and ready for hydraulic test of 150 lbs. per square inch. On the pump being set to work the first boiler split through the cold steel plate, the longitudinal crack being about three ft. long, the pressure reached being 140 lbs. The whole of the boilers were, we understand, thereupon condemned. It was determined, however, to proceed with the test, and three more boilers were easily burst with pressure varying, we are told, between 80 and 140 lbs. The plates were of Cammell's steel. This experiment will go far to cause the total rejection of steel by shipowners as a material for boilers. It is also stated that experiences recently acquired are all against steel as regards the durability of furnace plates, and some eminent marine engine builders will not employ it on any terms.—*Iron Age*.

A CHEAP HAMMOCK.—Take a piece of Manila matting from two or three yards long and a yard and a half wide, hind or bend the ends firmly, then fasten each end to a piece of timber. These pieces should be 5 ft. long, 2 inches thick, and should have holes bored about three inches apart the whole length. The matting is fastened by passing heavy twine from matting to hole, hack and forth, really sewing the matting to the wood. For each end of the piece of wood larger holes are bored, through which pass ropes to hang the hammock between two trees. This makes a cheap, comfortable and safe hammock. Being hung from four corners there is no danger of rolling out, and half a dozen children can swing in it at pleasure.—*Journal of Chemistry*.

A COLORADO PHENOMENON.—A large tidal spring has been discovered about six miles from Rico, says the *Gilpin county Register*, which is a curiosity. The spring is about 25 ft. in diameter. In the morning it is brimful of water and at evening it is perfectly dry. The water is remarkably clear and cold. It effervesces constantly, as do all the numerous springs in that neighborhood.

TO MAKE SELF-SHARPENING HORSESHOES.—Self-sharpening horseshoes are made by the simple expedient of rolling a steel plate in the center of the iron from which the shoe is made, so that the calks of the shoe have a hard steel center, and as the soft iron wears away by use the sharp steel is left to prevent slipping.

Vertical vs. Inclined Shafts.

Our correspondent, Mr. Frederick M. Amelung, in a recent letter, when speaking of a certain mine, made use of the following expression: "A new inclined shaft, following the dip of the vein, has been started." It is my opinion that this is false management, since the vertical shaft would answer the purpose far better, be free from water, and enable the mine to be worked in a systematic manner." Whereupon a correspondent in the *Silver World* of July 10th becomes indignant, and writes to that paper, saying that inclined are better in all respects than vertical shafts, and summarizes their advantages as follows:

"Any miner of Capt. Cruse's experience knows full well the superior value of inclined shafts for operating on fissure veins which have a dip, both for economy and systematic working, for the following reasons:

"First—An inclined shaft follows the course of the lode and proves its value as depth is gained, and not infrequently mineral is found in such quantities as to pay the whole cost of sinking, and in all probability the Ule shaft will be found to do, thus saving great expense to the owners.

"Second—All the cost of driving crosscuts to intersect the lode as in the case of vertical shafts is saved.

"Third—An inclined shaft being on the vein, as soon as deep enough, stations can be cut, levels can be extended, and thus the mine can be systematically and expeditiously developed.

"Fourth—The cage or bucket, as the case may be, for hoisting, comes down directly to the stations, flats or levels where the mineral is broken, thus obviating the necessity of taking the mineral in cars through long crosscuts to a vertical shaft.

"Fifth—It gives far better ventilation and air to the mine.

"Sixth—There is no more water than in a vertical shaft.

"Seventh—The inclined shaft can be sunk to a great depth and yet be in proximity to the lode; whereas, in a vertical shaft, as depth is gained, it departs from the vein until further operations prove impracticable."

Where the object of work is to explore a vein, especially in a new district, and where time is limited, there can be no question but that the incline following the lode is the most advantageous. As the vein is usually wetter than the country-rock, the incline on the vein is generally more troubled with water than the vertical shaft; but when it comes to permanent work (not exploration), the greater speed with which hoisting can be done in a vertical shaft, the less length required to attain a given depth, and consequently the less amount of columns, pipes, pump-rods, guides, rope, etc., required, are all in favor of vertical shafts. The great variations in the dip of a vein at different points is but one of the difficulties met with in making an incline on the vein a convenient shaft for permanent work. But a simple reference to Comstock practice—unquestionably the best in metal mining in this country—and the more and more general adoption of vertical shafts in the place of inclines in the anthracite coal mines, where a single shaft will turn out 1,500 to 2,000 tons in 10 hours' work, shows the practical recognition of advantages of the vertical shaft over the inclined one for regular work. This, however, does not affect the claim for superior economy and speed in exploring a vein by adopting an incline instead of a vertical shaft. So that each has its appropriate place, and neither is the best under all circumstances. —*Engineering and Mining Journal*.

THE DESTRUCTION OF GAME FOOD.—So long as America continued in the occupation of the aborigines, the order of nature was apparently but little disturbed. The buffalo and deer, the wild fowl and turkeys, furnished abundant food to the savages without serious encroachment upon the fertility of nature. In savage life there appears to be no wanton or unnecessary destruction of the natural means of support. It was reserved for the civilized white man to carry on wanton against this bounty of nature, and to kill and destroy, without thought or study of those imperative laws under which nature holds in trust, the food supply of man. From the first settlement of this country, the process of eradicating and annihilating the useful animals, birds and fishes natural to the country has been carried on with an energy and success, but too characteristic of the Saxon race. Large tracts of land have been entirely depopulated of their animals and useful birds. The buffalo on his native plains has become an object of rare curiosity. Deer are limited to the remotest mountain ranges or extensive tracts of barren woods. The wild fowl which swarmed in New England during the first settlement of the country, and for a long time afterwards, have almost disappeared. The last wild turkey was killed in Massachusetts nearly half a century ago. There is probably no sportsman living who has killed a grouse on Martha's Vineyard, the last refuges in the northeast of that most valuable bird. Plover still migrate, though in diminished numbers, from their breeding places in the far North to their winter homes in the South, but they carefully avoid the northeastern coasts. No one in this generation has seen a wild swan alighting on the waters of Massachusetts. They once abounded there. Even the wild geese find no resting place there, but are expelled as if they were tramps and vagabonds. —*International Review*.

USEFUL INFORMATION.

"Neptunite," the New Cloth Preservative.

The invention—already noticed in these columns—of a new compound to be applied to clothing, feathers, silks, etc., to render them capable of defying any injurious action from water, ink, lemon juice, coffee, etc., seems to be creating quite a stir in New York. It is claimed that the inventor's assertions as to its remarkable qualities were fully carried out by experiments recently made, and at which Mr. Thurlow Weed and a number of press representatives were present. The solution is said to be very rich in solids. By heating this solution until it changed into a gas and then placing in it the goods to be operated upon, every fiber of the material became saturated and coated with an elastic layer of the solution, which is wholly impervious to water. This coating is light, impervious and elastic, and strongly resists all the elements which tend to destroy fabrics. It gives a supple body and elasticity to the goods, and prevents all absorption of water. Yet the goods are not vulcanized, for they may be boiled without affecting the coating upon the fibers. The goods are rendered neither air-tight nor water-tight, but simply water repellent. Fabrics treated with this solution are unaffected by any stains, and even resist the action of acids.

During the experiments above alluded to a stream of water was directed first upon a carpet and then upon a piece of broad dress goods without "wetting" it. A gentleman's silk hat was dipped into the water, and cups of water were afterward poured upon it, but the silk was not disturbed. The experiment was greeted with great applause. It was followed, however, by one which quite overshadowed it. Two ladies' hats, so beautifully and delicately constructed, were subjected, flowers, laces and all, to the same ducking that had been bestowed upon the gentleman's hat, and yet no difference in their appearance could be detected. Ostrich feathers were dipped into the tank without even changing the curl in the feathers. Kid gloves and finally a number of ribbons were all successfully tested. Having finished with the water, lemon juice, coffee, claret and finally ordinary writing ink were poured upon the fabrics, without affecting them in the slightest degree. The ink rolled around upon a piece of pink silk like little black beads. The different liquids broke into little globules and rolled about upon the goods like mercury on a piece of glass. The inventor said that every effort had been made to do away with the coating after it had been formed, and that such efforts had proved unavailing. It made goods wear longer, and prevented silks from wearing "shiny."

A NOVEL ICE MACHINE.—A correspondent at Council Bluffs sends to the *Scientific American* a refreshing account of a car which came in on the Chicago & Northwestern railroad, the axle laden with icicles several inches long and the running parts covered with solid ice, which had formed there with the thermometer at 86° in the shade. The mystery is soon solved when he tells us that the car was loaded with gasoline, which was leaking through the bottom of the car. Gasoline, being extremely volatile, of course evaporated with great rapidity, and thus produced, as every volatile liquid does, a diminution of temperature, a principle made use of in all ice machines. The production of ice by the evaporation of gasolins, remarks the editor, is not so rare as our correspondent supposes. A harrel of gasoline exposed to the air on a warm summer day frequently has a crust of ice or snow around the bung and wherever any escape of the gasoline can take place. A current of air blown over the surface of a volatile liquid causes it to evaporate more rapidly, and in the case mentioned above such a current was caused by this motion of the train. As soon as the surfaces were cooled below the dew point, moisture from the air began to be deposited, which was frozen when the temperature reached 32° Fahr.

TO MAKE TEST PAPER.—The *Electro-Metallurgist* says that a useful test paper may be made by boiling one pound of leaves of the red cabbage in one pint of water for some time, and then straining the blue liquor through muslin. Evaporate to about half its bulk; place layers of white blotting paper in the liquid, and then hang them up to dry. Acids change the blue color of the paper to red, and alkalis turn it green. This is a very good substitute for litmus paper.

CAREFUL PRINTING.—In an article comparing American wood engraving with English, the *London Examiner* says, that if printed "with extraordinary care, on heartily prepared paper," some of the "blocks in English magazines would equal those which now appear in *Scribner*." It attributes more than one-half of the success of the wood cuts in *Scribner* to the printing and paper. This printer of *Scribner* is Mr. De Vinne, who is author of a "History of Printing."

IMPROVED BLEACHING PROCESS.—An improvement in the process of bleaching vegetable fibers has been made, which is said to consist in adding margarine, stearic, or oleic acid, or the mullage of flax or Panama bark to a hazy bath of alkali, or chloride of lime. This, it is claimed, limits the destructive action of the chloride, and promotes the solution of the gummy and resinous matters that adhere to the raw fiber,

VARNISH FOR FOUNDRY PATTERNS.—A varnish for foundry patterns and machinery has been introduced in Germany, the advantages claimed for which are that it dries as soon as put on, gives the pattern a smooth surface, thus insuring an easy slip out of the mold, and prevents the patterns from warping, shrinking or swelling, as there is perfect imperviousness to moisture. The preparation of this varnish consists in placing in a vessel 50 lbs. shellac, 10 lbs. Manila copal, and the same quantity of Zanguibar copal. This is heated by the external application of steam for four or six hours, being stirred in the meantime constantly. There are then added 150 parts of the finest potato spirit, and the varnish heated during some four hours to 190 Fahr. This liquid is then dyed by the addition of orange color, and can be used for painting the patterns. When used for painting and glazing machinery, the varnish may consist of 35 lbs. shellac, 5 of Concorial copal, 10 of Zanguibar copal, and 150 parts of spirit.

RED PRINTING INK. according to the *Engineer*, may be made in this way: Boil linseed oil until smoke is given off; set the oil then on fire and allow it to burn until it can be drawn out into strings half an inch long; add one lb. of resin for each quart of oil and one-half lb. of dry, brown soap cut into slices. The soap must be put in cautiously, as the water in the soap causes a violent commotion. Lastly, the oil is ground up with sufficient pigment on a stone by means of a miller. Vermilion, red lead, carmine, Indian red, Venetian red and the lakes are all suitable for printing inks.

NICKEL is said to be more infusible than iron, more malleable, more ductile, tougher, and quite unaffected by atmospheric influences. M. Fleitmann has found that when melted it absorbs some carbonic acid, and if a small quantity of magnesium is then added, the metal becomes remarkably ductile and malleable. It can be drawn out into very fine wire, or beaten into extremely thin leaves, and can readily be welded either to nickel or iron.

A DOOR standing open, which would readily yield on its hinges to a gentle push, is not moved by a cannon ball passing through it. The hall in passing through, overcomes the whole force of cohesion among the atoms of wood, but its force acts for so short a time, owing to its rapid passage, that it is not sufficient to affect the inertia of the door to an extent to produce motion.

GOOD HEALTH.

Bad Water as a Cause of Disease.

A correspondent of the *Scientific News* says: "It is not strange that doctors and old women believe that fevers are produced by drinking what is supposed to be unwholesome water. Any absurdity will be generally believed whenever it has been preached enough. And the bad water theory has been preached from generation to generation, perhaps from Adam's time down to date.

"Doctors frequently examine water with a microscope and see small 'dangerous' animals in the water, and report this fact with the bad cases of sickness 'thus produced' to medical journals, who innocently publish it all, and, without considering the fact that, with the same instrument, they can see as many animals in any and all water that healthy people drink.

"Now, the facts are, that any person may drink their fill out of any stagnant pool of swamp water with tadpoles, animalcules, lizards and all, without receiving any injury therefrom, simply because the stomach has a way of disposing of the animals; but the lungs have not. Hence, persons should cease to breathe while drinking. The lungs may inhale more than what can expel.

"The water was no worse while all Memphis was having the yellow fever than at any other time, and had nothing to do with producing the fever. While the prairies of Illinois were being broken, the people had more fevers per acre than in any other country, simply because there was more vegetation per acre rolled under to rot and poison the atmosphere; and, during the prevalence of fevers in Illinois, the water was no more dangerous than now.

"There are no fevers or agues in any country where the soil is generally poor, no matter what can be seen in the water.

"I believed the bad-water theory until I commenced to run a pump factory, which gave me an opportunity to know what people had in their wells. I did not need the microscopes to see the slippery remains of dead toads, snakes, poisoned rats, skunks and woodchucks. Some people had a well and privy in a back yard, some respectable distance apart on top of the ground, but they were practically all one thing in the same strata of gravel at the bottom. I expected to see the people get sick (as they should) from using such water; but never knew of a case of the kind, which shows that people may live healthy on pure air and horribly bad water."

The editor of the *Scientific News* comments on the above as follows: "Our correspondent is at fault in his assumption that visible organisms, dead or living, in water, are supposed to be a cause of disease. The poison of typhoid or of yellow fever is no less a poison because invis-

ble, and the former, at least, has been as distinctly proved to be carried by infected water as the poisons of yellow fever has been proven to be transported in clothing."

Spread of Disease by Earthworms.

Recent researches by M. Pasteur appear to throw considerable light on the origin of anthrax, or aplenic fever, and allied diseases, which attack cattle, sheep, etc. (If animals, why also may not man be seriously affected by the same mode of spreading other disease germs?) When an animal dies of anthrax it is not uncommonly buried on the spot. The conditions of putrefaction prove fatal to the small parasitic organisms, or bacteridium, which is abundant in the blood at death. The gas given off causes it to break up into dead and harmless granulations. But before this can occur not a little of the blood and humors of the body have escaped into the ground about the carcass, and here the parasite is in an aerated medium favorable to the formation of germs. These corpuscular germs M. Pasteur has found in the soil, in a state of latent life, months and years after the carcass was buried, and by inoculation of guinea pigs with them, has produced anthrax and death. Now it is especially notable that such germs have been met with in the earth at the surface above the place of burial, as well as near the body.

The question arises: How came they there? And it would appear that earthworms are the agents of conveyance. In the small earth cylinders, of fine particles, which these creatures bring to the surface and deposit after the dews of morning or after rain, one finds, besides a host of other germs, the germs of anthrax. (The same process was proved also by direct experiment; worms kept in ground with which bacteridium spores had been mixed were killed after a few days, and many of the spores were found in the earth cylinders in their intestines.) The dust of this earth, after the cylinders have been disintegrated by rain, gets blown about on the neighboring plants, and the animals eating these thus receive the germs into their system. It is suggested that possibly other disease germs, not less harmless to worms, but ready to cause disease in the proper animals, may be in like manner conveyed to the surface in cemeteries. The *Scientific American* suggests that this should also furnish a fresh argument for cremation. The practical inference as to anthrax is, that animals which have died of this should not be buried in fields devoted to crops or pasturage, but (wherever possible) in sandy, calcareous ground, poor and dry—unsuitable, in a word, for worms.

The value of the eucalyptus in allaying the unwholesomeness of the malarial districts is very positively affirmed in a recent number of *London Nature*. The testimony in support of the efficacy of eucalyptus in this respect, the writer asserts, are too convincing to be doubtful. In malarial districts, where the fever-tree abounds, fevers are unknown, and in Algerian Corsica, where the experiment of planting the trees on the strength of their reputed virtues was systematically made some years ago, malarial fevers have entirely disappeared. From Algeria, especially, the evidence of its virtues is very convincing. Consul Playfair reports, for example, that large tracts of land have been transferred by the agency of the fever-tree, and that, wherever it is cultivated, fevers are found to diminish in frequency and intensity. M. Gimbert recently made a report of like tenor to the French Academy. The pestilential district about the city of Rome, known as the Campagna, had, until lately, a world-wide reputation as a veritable hot-bed of deadly fevers. It is now affirmed to have vastly improved in wholesomeness, in consequence of the presence of large numbers of eucalyptus introduced some years ago by order of the Italian government.

SINGULAR EFFECTS OF NITRO-GLYCERINE.—A correspondent of the *British Medical Journal* gives, in the case of a lady suffering with cramps in the stomach, something less than a drop of a 1% alcoholic solution of nitro-glycerine. In two minutes the pulse fell from 140 to 50; a clammy sweat covered the patient's features, and she became senseless. Stimulants to the nose and brandy were quickly given, and in about three minutes more she began to recover. The pain was completely gone, and did not return all that night or the following day. The patient said she felt like two people, and so strong was this impression that, though perfectly rational in her conversations and unexcited in her manner, she could not shake it off, but frequently checked herself when about to make allusion to her imaginary double.

MEAT FOR INVALIDS.—The following is a good method of rendering raw meat palatable to invalids: To 8½ oz. raw meat from the loin, 2½ oz. shelled sweet almonds, 17 oz. shelled bitter almonds, and 2½ oz. white sugar—these to be beaten together in a marble mortar to a uniform pulp, and the fibers separated by a strainer. The pulp, which has a rosy hue and a very agreeable taste, does not at all remind one of meat, and may be kept fresh for a considerable time, even in summer, in a dry cool place. Yolk of egg may be added to it. From this pulp, or directly from the above substances, an emulsion may be prepared, which will be rendered still more nutritious by adding milk. A small quantity of wine or tincture of cinnamon may be added, if desired.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Inter-Oceanic Ship Railway, 145-150. The Week; Women as Insane Asylum Physicians; More Thorough Work; A New Industry, 152. The Mears Chlorination Process; Vast Importance of the Cotton Crop; Tea Culture in the United States, 153. Notices of Recent Patents; San Francisco Plating Works; Is South America Rising or Sinking? 156.

ILLUSTRATIONS.—Diagrams Showing the Disposition of Weight and Buoyancy of Vessels in Different Positions, 145. Tea Plant One Year from Seed, as Grown in Japan, 153.

CORRESPONDENCE.—Mines in and Around the Silver Peak Salt Basin, Nevada, 148.

METEOROLOGICAL.—Application to the Distribution of Rain, 148.

MECHANICAL PROGRESS.—To Obtain Well Defined Castings; A Substitute for the Crank; Shipping of Locomotive Driving Wheels; Singular Break in a Shaft, 147.

SCIENTIFIC PROGRESS.—Changes in the Earth's Figure; The Height of the Atmosphere; New Polarizing Prism; Microscopic Examination of Ice, 147.

MINING STOCK MARKET.—Sales at the San Francisco Stock Boards, Notices of Assessments, Meetings and Dividends, 148.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado and Idaho, 148-149.

USEFUL INFORMATION.—"Neptunite," the New Cloth Preservative; A Novel Ice Machine; Varnish for Foundry Patterns, 151.

GOOD HEALTH.—Bad Water as a Cause of Disease; Spread of Disease by Earthworms; The Value of Eucalyptus; Singular Effects of Nitro-Glycerine; Meat for Invalids, 151.

NEWS IN BRIEF on pages 156 and other pages.

The Week.

Since our last issue there has been a noteworthy occurrence in the arrival at this port of the *Ho Chung*, a Chinese steamer. She is a small craft of British build, and one of some 30 steamers, most of which are larger than the *Ho Chung*, owned by a Chinese company. On entering at the Custom House the steamer had to pay an extra duty of 10% on her cargo and an alien tonnage tax of \$1 per ton. She brought a few white passengers and only seven Chinese.

Recently the State Board of Equalization gave notice that it intended to raise the valuation of real property in this city 10% over the county assessment. Against this contemplated increase, the Board of Supervisors promptly protested; for it is the prevailing belief among our citizens that the assessment is now quite high enough. It is stated further, that an advance of 25% throughout the State is meditated by the Board of Equalization.

The visit to this city of the President of the United States will be an interesting event. His reception and entertainment will be participated in by the great body of our citizens. It will be arranged by a committee of 200 citizens, selected equally from the great political parties; and from this General Committee there will be selected an Executive Committee to carry out the details of the reception. A special train will fetch the President here on the 8th inst. Gov. Perkins will welcome the Presidential party at the State line. On the 9th inst., the anniversary of our admission as a State, President Hayes and Gov. Perkins will be received at Oakland. And later, the President will receive the congratulations of his fellow citizens at the Palace Hotel.

The Industrial Exhibition is now in its fourth week, and has been a fine success. The coming week will be the most interesting period of the fair, and the concourse of visitors will doubtless be largely increased. Among the many notable features of the exhibition, the display of mining apparatus is the most conspicuous. Our mining machinery is unrivalled, and it challenges the admiration of every intelligent visitor. To those interested in the great industry, that exhibit of machinery alone is worth a week's attention.

Women as Insane Asylum Physicians.

Hitherto we have assigned to women certain positions in society, and have questioned the wisdom of any change. If they failed to fill their places creditably, there has been no hesitation to tax them sharply for their incompetence. It was conceded that everything was possible for man; but woman's capacity was apparently gauged at the beginning, and metes and bounds were fixed as the limits of her progress. This assumption of inferiority has grown out of the belief that her intellect is less profound than man's, and that she is more uniformly ruled by feeling, and is more impulsive and less reflective. Grant that this assumption is true: yet this very difference in mental and physical qualities, this apparent weakness, constitutes at once woman's grace and strength. Her tenderness, her devotion, her patience, her large sympathies, and her instinctive love of good—which is usually her equivalent for right—spring from these minor differences of sex. Fortunately there is a tendency to give to woman an opportunity to change and enlarge her scope of usefulness. If her sentiments respond to some necessity of her condition, it dictates ought to be respected. By all means give woman a chance to broaden her sphere of active and useful duty. At the best she is heavily weighted in the race of life. It ought to be the duty of man to see "that not another grain is piled upon that load beyond what nature imposes; to take care that injustice is not added to inequality."

We make this plea in behalf of the employment of women, who have been trained as physicians, in asylums for the insane of their sex. The number of women who have had a special training in some approved system of medication, is growing constantly; and their practice, we may remark, fully establishes their fitness for the general business of the physician. The care of insane women in hospitals and asylums, which has long been left to women attendants under the supervision of men, is coming to be under the supervision of women also. Only a short time ago a paper in Chicago published a list of six hospitals, most of them large establishments, where one of the assistant physicians is a woman; and in one of them, the new Eastern Pennsylvania hospital, Dr. Alice Bennett is to have the entire medical direction of the women who are patients. Another woman, Dr. Mary A. Cleaves, of Davenport, Iowa, has lately been appointed to take charge of the woman's half of the old State asylum at Harrisburg, in Pennsylvania. It is said that the masculine superintendents shake their heads at these radical innovations, and hint that they may be compelled to leave; but, as the *Springfield Republican* remarks, the common-place wisdom of the old judge who decided that "a man should not blow out his candle till he got his hand on his night-cap," is still in force among men in office. Of the entire fitness of Dr. Cleaves for the appointment there is ample testimony. A correspondent of the *Chicago Tribune* says of the lady: "Dr. Mary A. Cleaves for three years was assistant physician in the hospital at Mount Pleasant, Iowa, and since has been an efficient member of the board of trustees for the same institution. Last year she read a paper before the conference of charities in Chicago, which was commended for originality of thought and practical ideas." And the *Davenport Gazette*, the chief journal of the city where Miss Cleaves has been in general practice, and where her hospital record is well known, bears this testimony to her qualifications:

"Little if anything can be added to the wisdom of the choice thus made. Here in Davenport Miss Cleaves has the confidence of every one, and the profound respect of her associate physicians. Her ability is recognized, and her work in the practice of her profession has been followed with pronounced success. In the wider field to which she has been called, opportunity will be given for the full range of her talent, which amounts to genius."

There are, of course, great difficulties in the positions in which these women have been placed, and too much must not be expected from them at once. It has been confessed that the most experienced physicians know little enough about "ministering to a mind diseased," little enough about insanity on its most important side, that of cause and recovery. Time and experience, and study will complete the fitness of women for the delicate and responsible duty. In the meantime, there can be no reasonable objection it seems to us, to the employment of women in asylums and hospitals devoted to their sex. The presence of a woman would help greatly to engage the confidence of her stricken sisters, and her womanly intuitions would more readily perceive the cause of the malady, and suggest the proper treatment towards a cure. Cases may be imagined where such a result would be impossible in the hands of the most accomplished physician of the other sex. The subject of employing women in the care and treatment of the insane of their own sex is worthy of serious consideration; and we hope it will receive such humane and intelligent thought here in California as elsewhere.

WYOMING has a population of 21,900. In 1870 it was 9,276.

More Thorough Work.

The managers of mining property in Bodie are doing more thorough work. At first, it would appear, their means for developing their mines were altogether inefficient; but, after several years' discipline in the hard school of experience, they are beginning to learn to adapt efficient means to proposed ends. In relation to this subject the *Free Press* says: A year and a half ago the writer advocated the immediate erection of heavier machinery for the Bodie mines. Enough was determined to warrant such conclusions. Except in the case of the Standard, nothing of the kind was done, and even that company confined this new addition to a pump. During all this interval, however, work has been retarded because of the hoisting power being out of proportion to the demands upon it. So much ore has had to be raised, aside from the waste rock, that the engine is all the time over-taxed. But for this it is safe to say that the 1000-ft. level would have been far advanced in exploration, instead of the shaft dragging along about the 900-ft. station. The Bodie and Mono companies lost a year's valuable time fooling with expensive steam pumps. One year ago stocks were up, and the work of collecting assessments was an easy matter as compared with the present times, so that a grand opportunity was lost by not taking time by the forelock. Other companies are in the same dilemma regarding depth or the want of it, and the means and machinery to effect it. Fortunately the Noonday stepped in with a solid proposition for the south end of the district, and at the eleventh hour the Bodie and Mono start in to do what should have been inaugurated two years ago, when the big boom in the history of the district was all the rage and sensational dividends were in order. If the Standard can manage to drain the north country to 1,000 or 1,200 ft. deep, until the Bodie-Mono gets down accordingly, all may be well with several other important enterprises in the neighborhood. Fortunately the Noonday-Red Cloud operation has 400 ft. of depth to begin with, so that it will not require so long a time to get extensive pumping facilities quite below any and all present depths at the south end.

COMPETENT ENGINEERS WANTED.—It has been the common practice to speak of the fatal disaster which occurred in the Hudson River tunnel, by which the lives of 23 men were sacrificed, as an "accident;" whereas it was undoubtedly caused by the incompetence of those in charge of the work. It is safe to assert that that reckless and wicked drowning of unsuspecting workmen would never have occurred if the work had been under the direction of an experienced and skillful mining engineer. That tunnel, remarks the *Engineering and Mining Journal*, though an important work, and requiring the exercise of engineering experience and skill in its construction, is not one which necessarily involves great danger to the workmen engaged in it. From its inception, the work appears to have been directed by wholly inexperienced persons; and the same may be said of the efforts which have been made since the so-called accident to recover the bodies of the unfortunate men, or to make the connection between the tunnel and the shaft. It is the plain duty of the directors of the Tunnel company to secure a conference of competent engineers to examine and report upon the plans which have been proposed for completing the work, in order that a repetition of the late fatal blunder may not happen.

WOOD RIVER, IDAHO.—Mr. Thomas Allen, who has lately returned from Idaho, informs the *Territorial Enterprise* that the Wood River region is all the rage up that way at present among prospecting miners. He says the new mineral belt is some 75 miles in length, by 35 to 40 miles in width. While in most of this region the veins contain base metal or smelting ores, there is one section, at what is called Saw Tooth, where free-milling ores are found. There are now in the country some 3,000 people, who are divided up among half a dozen camps, generally dignified with the name of "city," as Jacobs City, Galena City, Saw Tooth City, etc. Up that way they think they have a wonderful mine if they have a shaft down 80 or 100 ft. Most of the shafts are but from 15 to 50 ft. in depth. Several of the galena veins yield from 200 to 300 ounces of silver to the ton. Many Salt Lake men are interested in the Wood River mines; also, a considerable sprinkling of miners from Nevada and California.

A PLENTY OF MONEY.—In the whole history of Portland, says the *Portland (Oregon) Bee*, no such accumulations of money were ever seen as at present fill all depositories. Every bank is deluged with coin and greenbacks, and on good security any amount is obtainable at 10% per annum. Borrowers are, however, not plentiful, as most of the improvements in progress are conducted by those who have the means to continue them without being obliged to borrow. Notwithstanding the increase in the price of material, there are fully as many buildings in course of erection this year as there was last at the same time.

A New Industry.

There is no place in the world, probably, where there is so great a consumption of what are known as "high explosives," as on this coast. Powders of this character are used in all of our mining operations very extensively, both in quartz and gravel. The explosive which will produce the greatest effect with the smallest labor or time employed in boring holes to rcsolve the same, is that which is demanded by the miners. When tonite was brought out in Europe the reports from it were such as to attract the attention of capitalists here, and the well known mining engineer, Hamilton Smith, Jr., went to England to investigate the subject. He was abundantly satisfied that the claims made for the explosive were sustained by the facts, and on his return he made a report on the strength of which "the Tonite Powder Company" was organized in this city.

The company have now begun to take active steps toward manufacturing the new explosive. Very extensive works are now in process of construction at Stage station, on the Northern railroad, between Berkeley and San Pablo, at which point there is a convenient place for a wharf on the bay shore. The buildings which are being erected, are of an entirely different character from those usually put up for powder works, being of a substantial and durable character, the company having confidence that they are in no danger from explosion.

The Risdon Iron Works are now building the machinery, consisting of an 80-horse power engine, centrifugals, pressing machine, etc. There is a good deal of machinery required, and it will cost upwards of \$50,000. They will soon be going ahead full blast, and have their powder on the market.

The process of manufacturing is essentially different from that of the nitro-glycerine compound. In them a day will finish a batch of powder. It takes a week before the entire process of manufacture of tonite is completed. Tonite has proved truly very successful in England, and is spoken of as "the explosive of the future." Its great points are its increased strength, absence of fuses non-liability to freeze, and its safety from explosion.

PLACER MINES AT MEADOW LAKE.—For some time there have been rumors of the existence of placers at Meadow Lake, in Nevada county, and of their successful working by a party of Italian miners. The *Nevada Transcript* has endeavored to trace the rumor to a trustworthy source, and has learned that while a party of men from Truckee was at Meadow Lake it met a number of Italians, who, on being questioned, stated that for several years they have been engaged in placer mining at a point near the line of Washington township, from which they had realized large pay. The water supply was meager and the season of work short, but the men appeared to be well satisfied with the results of their labor. Beyond this statement nothing further has been learned respecting the existence of placers in that district.

IMPRISONED IN A MINE.—Day before yesterday, about noon, says the *Enterprise* of August 24th, the giraffe got off the track of the incline at the Hale & Norcross mine; and got so wedged in against the timbers that it could not be moved. There were 20 men on the 2400 level that had gone down at 7 o'clock in the morning, who were left without means of reaching the surface, except by climbing the incline. About 2 o'clock yesterday morning 17 of the number performed this feat, climbing up to where they could go out to the Chollar-Norcross-Savage shaft, but there being a very hot place to pass through, three of the men would not undertake the trip, but remained below until the giraffe was again put in motion, which was about noon yesterday. It was not so hot below as to in any way injure the men, but their position was a very uncomfortable one during their imprisonment.

LARGE FOREST FIRES.—According to the *Shasta Courier*, the great fire which has been raging between here and Clear creek for several weeks past, still continue its ravages, filling the atmosphere with a dense smoke. Parties who are cutting wood this side of Clear creek state that the fire is set out and kept going by parties whom they cannot get sight of. While these wood-cutters were at dinner last Saturday a fresh fire was started by some unseen person near their wood, and they had hard work to keep their camp and outfit from being consumed. A close watch and bullets from a rifle may reveal who it is that spreads the fire.

THE Manchester *Guardian* is informed by its London correspondent that Herbert Spencer, the eminent scientific and philosophic writer, intends next year to make a tour round the world by way of the United States and Japan. He will devote two years to it, taking sociological observations at the more important points on the route. One or two scientific friends and one of his secretaries will accompany him on the tour, which will be the immediate preliminary to the completion of his philosophical system as originally planned.

The Mears Chlorination Process.

The new chlorination process of J. Howell Mears, M. D., is alleged to be the result of years of study and experiment on gold-bearing ores, especially on those classed as refractory sulphides. Ores of this character have been reduced by this process for some two years with such success that the resulting tailings contain nothing of appreciable value; and the yield of bullion is frequently equal to the value of the ore as determined by fire assay. It is pronounced to be an improvement on the older and approved processes of chlorination, including the Plattner; for it not only gives the best result in one-tenth of the time required by the latter process, but it does so at a small cost. Dr. Mears maintains that the advantages of his improved process have a wide application, and that it will largely supersede amalgamation in all gold quartz mining. It obviates the large loss of fine or "float gold," which is inseparable from amalgamation, and it has overcome the chief obstacles to the use of previous processes of chlorination by lessening the expense, and reducing the time to the minimum. That these obstacles have been overcome by the process of Dr. Mears has been demonstrated on a working scale in several mills. These repeated demonstrations have perfected the detail and determined the practice of the Mears process; and now that invention may be said to give assurance of a new departure in the methods of obtaining the gold from refractory sulphides.

The Plattner process, the merits of which are great, is too well known to require further mention. The Mears improvement—indeed, it is called the "Mears-Plattner process"—derives its specific character from compressed chlorine in a revolving cylinder containing the gold-bearing roast-mass. The advantages claimed for this improvement are: 1st, expedited action, by which time is greatly reduced; 2d, contraction of the operating area and appliances, giving economy in material, in hauling, and in the outlay for plant; and 3d, a close, indeed a closer extraction of the metal than is obtained by the older process according to Plattner. Following is a concise description of Dr. Mears' system:

1. Chlorine is generated in the usual manner by sulphuric acid, peroxide of manganese, and common salt, or, if preferable, by hydrochloric acid and manganese. The generator of the ordinary construction, and of a size proportioned to the work proposed.

2. A gas-holder, or gasometer of metal, properly protected and of moderate size, is used, as like tanks for illuminating gas, and for a like purpose, as a magazine to hold a constant supply.

3. Connection pipes of lead intermediately connecting a specially-devised force pump with the gasometer and a strong reservoir, into which the force pump compresses chlorine to the required degree of pressure, thereby also obviating the necessity for a large gasometer.

4. Connecting pipes, adjustable to a cylinder of iron lined with lead, the cylinder revolving on trunnions centered on the heads, and resting in boxes firmly seated on the iron frame support, one trunnion being hollow, to which the connecting pipe is adjusted. Central on the periphery of the cylinder a manhole fitted with an adjustable cover. All assailable parts protected with sheet lead, and the parts firmly bolted together, and capable to resist a pressure much greater than the working maximum, and indicated by an attached pressure gauge.

5. Filtering vessels with prepared bottoms, transportable on wheels, into which the chlorinated charge is dumped from the cylinder, water added, and from which the liquid or solution containing auric chloride is filtered or leached out until a test shows no trace of gold.

6. Vessels or receivers for the solution and for precipitating according to the method practiced.

Having established this complete plant, the operation of chlorination is carried out as follows:

1. A charge, consisting of 2,000 pounds dead-roast, is put into the cylinder, and to this 125 gallons of water added. The thorough mixing is then effected by revolving the cylinder. After having exhausted the atmosphere, to prevent adulteration of the chlorine, the charge of chlorine from the pressure reservoir is admitted until the gauge indicates the required density. The chlorine is then shut off, and the cylinder kept revolving from 30 to 60 minutes.

2. The chlorine having by this time thoroughly dissolved the gold in the dead-roast, the excess of gas under pressure is allowed to pass off either into the gasometer for re-use, or into a newly-charged cylinder to chlorinize another ton of dead-roast. The gas remaining in the water, held by absorption, is expelled or drawn off by means of a vacuum produced by adjusting the connections with the pump. The chlorination being finished and surplus gas discharged, the whole contents are run into leaching vats.

3. The leaching is finished when the liquid no longer shows a trace of auric solution in the sample tested.

4. This solution is then ready for the precipitating agent. If the sulphate of iron, it is added until a test sample shows no discoloration on adding a few drops of the sulphate. If charcoal, this auric solution is run through harrels properly filled with carbon, two or more being

used for absolute security that the whole of the gold has been deposited.

5. In this first case the precipitate is washed, some sulphuric acid being used to clear it of contaminating matters, and then smelted into an ingot with borax, etc. Or, in case carbon is used, the rich gold concentrate is dried and incinerated, the ashes washed out, and the gold smelted as in the previous case.

By following these simple, progressive and systematic operations, the entire contents of the numerous dead-roast are extracted and put in the form of bullion; and if the operations have been conducted with this care that the process demands and makes easy, there will scarcely be a trace of gold left in the concentrates, certainly not over 50 cents a ton. In an establishment where several tons of dead-roast are worked continuously, only, or mainly, that chlorine absorbed by the water is wasted.

The first consideration in this process of chlorination is a perfect roasting of the mineralized ore. The furnace formerly preferred was a modified construction of the reverberatory, in

Vast Importance of the Cotton Crop.

Mr. Edward Atkinson, a most competent authority on matters relating to political economy, says that the present cotton acreage of the Southern States covers less than 2% of the cotton-growing area of the United States; and that we do not begin as yet to appreciate the magnitude of the wealth to be obtained from the culture of cotton in this country. He estimates that the present crop of cotton will be at least 25% larger than the largest crop ever raised by slave labor—that is, it will exceed 6,000,000 bales. That amount of cotton, he says, will produce 3,000,000 tons of seed, over and above that needed for planting, which will yield 90,000,000 gallons of oil, 1,300,000 tons of mill-cake, and 1,500,000 tons of hulls suitable for making paper. Each ton of oil-seed meal will keep five sheep six months. Thus the crop of cotton seed will not only support mil-

Tea Culture in the United States.

By the efforts of Gen. Le Duc, Commissioner of Agriculture, tea culture in this country is coming upon a more promising commercial basis than ever before. The distribution of tea-plants from Washington has proceeded for a number of years and small samples of tea have been made in California and in some of the Southern States. There has been so much talk about tea and so little sewing-circles timber really produced that tea culture as an industry for this country has been looked upon by many as a sort of an industrial chimera. Since Gen. Le Duc has taken the subject in hand it must be acknowledged that tea growing has assumed more features of practicality.

We have just received from the East reports of an interview between a newspaper writer and the Commissioner of Agriculture upon the return of the latter from a visit to the tea plantations in the Southern States; and to illustrate the interesting statements which we have to make, we give an engraving of a young plant, leaf, stem and roots.

In his review of the history of tea growing in this country, Gen. Le Duc said that probably the largest number of plants collected by any one person are those collected by a Dr. Jones in Liberty county, Georgia, near Savannah, who some time before the rebellion undertook to raise a number of plants with a view of making tea. His plantation was practically abandoned, and after this war his daughter, Mrs. Scraven, prepared tea in a rude way from leaves picked from the trees. When, as Commissioner of Agriculture, I wished to promote the cultivation and manufacture of tea in this country, with a view of supplying our people with home-raised tea, and thus decreasing the importation of the article, I purchased from Mrs. Scraven plants and seeds for distribution, and I scattered these throughout the South. It is unnecessary to go into details at this time, and I will simply say that by great good fortune a Mr. Joho Jackson, who had for 15 years been cultivating tea in Assam, India, traveling in this country last spring, had his attention drawn to my efforts tending to encourage the cultivation of tea, and entered into correspondence with the department and visited me at Washington. The result was that Mr. Jackson took a trip through the South, visiting the various localities in which the tea-plant was growing, and was so entirely satisfied with the prospect of successful and profitable cultivation that he purchased the plantation of Mrs. Scraven, and commenced to establish a tea garden with the assurance that the department would aid him by all proper means. Mr. Jackson employed a large force of negro labor, put up some necessary houses, and has already 160,000 plants growing in 50 acres, which he proposes to increase to several hundred acres as rapidly as he can obtain proper seeds or plants.

I have but a short time since returned from an examination, assisted by Mr. Jackson, of a large area of South Carolina, in which are found many locations in which the soil and climate were pronounced by Mr. Jackson as exceedingly favorable for the production of the tea plant. This preliminary examination showed more land suitable for tea culture in the belt of country about 40 or 50 miles back from the coast, the best land being mostly situated in that portion which is regarded unhealthy for white people during the summer months, but not particularly unhealthy for the negro, who seems to live and thrive unharmed by the malarial atmosphere of the rich lands of that section.

For a number of years persons throughout the South owning one or more tea plants have made tea as best they knew how, but in a very crude fashion, bruising the leaves and drying them in a Dutch oven or even in the sun, and storing them away as a family supply of the fragrant herb, which they pronounced better than any they could purchase at the stores. Notably, this has been done in the last two years, since the publication and circulation by the department of a little treatise upon tea culture and manufacture. But no tea has been made of a commercial character until Mr. Jackson this spring commenced to manufacture tea in proper form, and sent it to the department as an evidence of what could be done, even with the old and neglected plants he had purchased with the Jones plantation. These teas are undistinguishable from the finest qualities of Indian teas on the market, and have been pronounced by the best tea-experts in this country and in London to be of superior quality and flavor. The prices offered for them are eminently satisfactory to the producer.

LARGE HORSES.—A consignment of horses, says the New York Tribune, has just been received in Boston from Normandy. The lot comprised 20 stallions and 6 or 8 mare colts, and is to be sent to Bloomington, Ill. Three of the horses weighed 2,010 lbs. each when shipped, and the rest averaged about 1,900. They are magnificent-looking animals, standing about 16 hands high, very stoutly limbed, and with heavy manes and tails. Three of them are valued at \$3,000 each, and the others at \$2,500 each for stock purposes. They are brooded with common Western stock, and the cross is an animal weighing from 1,200 to 1,400 lbs., and worth in the West from \$175 to \$200. They are used principally for draft horses, but are also easy drivers. They are noted for their docility and intelligence.

TEA PLANT ONE YEAR FROM SEED, AS GROWN IN JAPAN.

terrace or double hearths. Mechanical furnaces have been used with more or less satisfaction. At present the Mears Co. use a revolving hearth. In regard to this highly important matter of roasting, it may be said that any furnace which performs the work well may be selected for the purpose.

In stating the relative cost of chlorination by the Plattner and the Mears processes, the Mears Co. gives the estimates of Prof. Deetken, published in 1874, which are for California roasting, \$4.87; other work, including materials, \$6.23; total, \$11.10 per ton. Of this amount the cost of chlorination proper of dead-roast per ton, is given at \$2.21. The company assumes the present cost of the work in California to be 20% less than Deetken's estimates, and put the cost of chlorination, including materials and labor, at \$5 per ton instead of \$6.23; against this sum it places the cost of chlorination per ton of dead-roast by the Mears process, at \$2.25, based on the California rate; or, at the works of the company in North Carolina, where labor is cheaper, at \$1.91 per ton where the chlorine is not re-used; or, at \$1 per ton where the chlorine is re-used. Between these processes there is no difference in the cost of chemicals or other materials, or wages, the advantages of the Mears process consisting in the expedition of the operation, the conservation of chlorine and the close extraction of the gold,

lions of sheep, but it will return to the land the fertilizer needed to grow more cotton. These facts reveal at a glance the intimate relation existing between two of the great staples of the country—cotton and wool; and they suggest the immense possibilities of the future for both the North and the South. The development of the latter means business for the former. It is of the utmost consequence to the agriculturists of the North that a new and increased demand for the products of its industry shall spring up in our vast and sparsely peopled Southern States. They are filling up, fortunately, and are requiring more houses, and clothing, and utensils of all sorts—indeed, everything which our manufacturers can cheaply supply. Mr. Atkinson's proposed combination of the cotton and sheep husbandry ought to receive the most serious consideration. And he believes that a "cotton exhibition," during which all the facts he has stated and many others would be developed, would greatly stimulate interest in the direction he suggests.

PERSISTENT SNOW.—The Downieville Mountain Messenger, of August 28th, says there are several snow arches on the East Fork, about five miles above town. The largest is several hundred ft. long, spanning the river and completely covering it with a depth of solid snow to a height of nearly a hundred ft. Under these arches the water drips down in a steady shower.

The Florida Canal Project.

General Gillmore, who had been detailed to study the question of the feasibility of a ship canal from St. Mary's river, Fla., to the Gulf of Mexico, has embodied the results of his preliminary surveys in a report to the Secretary of War. General Gillmore does not think the Florida canal will be built, but he was directed to go over the ground in person, and he has made as complete a survey as the comparatively small sum allotted for the work permitted. Still, he regards the examination only as preliminary, and suggests that much additional information will have to be collected and numerous groups of shafts sunk in the swamps before the canal can be located and a reasonably exact estimate of its cost prepared. He is not positive that the St. Mary's river is superior to the Satilla for purposes of improvement for ship navigation, and recommends an examination of the Gulf coast in order that the best site for an artificial harbor may be selected. The great length of the line and the difficulties of access to intermediate localities have rendered it impossible for him to trace, with any degree of accuracy, the most available route between ocean and gulf. It is scarcely necessary, therefore, to consider the preliminary and alternate routes in detail.

The length of the canal route which Gen. Gillmore favors is about 169 statute miles, including a ship canal of 122 miles, with 34 miles of river navigation and 13 miles of deeper water from bar to mouth of the St. Mary's, and, on the other side, the entrance to the Gulf. The lowest estimate of the cost is \$50,000,000. The calculations for water supply are based upon a cross section of canal 80 ft. wide at bottom and 25 ft. deep, with a water surface 180 ft. in width. The section adopted has greater width at bottom and a depth and surface width somewhat less than that recommended by the technical subcommittee of the Paris Congress for the Panama canal. The ascent from the St. Mary's is made by means of seven lift-locks, each 15 ft. to the summit level, 108 ft. above sea level. Inland there are two locks, each of 10-ft. lift, and the level of the Gulf is reached by five locks of 15 ft. and one of 10 ft. From the mouth of the canal to the deep water of the Gulf a channel will have to be excavated and protected by jetties. There is an alternative project, by which the Suwannee river is used as a reservoir without any material saving in expense.

The principal benefits to be derived from the construction of the canal across Florida are fully considered in Gen. Gillmore's report. The route from New Orleans to New York will be shortened 497 miles; that from New Orleans to Liverpool, 412 miles. The voyage of a steamer of average speed would be shortened half a day, while the gain for sailing vessels would be considerably larger. The most liberal estimate of the amount saved in the consumption of coal and in ordinary running expenses is \$266,500. On this basis the tonnage dues through the canal would have to be made exceedingly light in order to attract business. The dangers of the passage through the Florida straits must also be taken into account, although the reduction in freight charges and insurance cannot be closely estimated. The calculation that \$894,000 could have been saved in floating property if the canal had been in operation during the five years ending June 30, 1879, bears upon this point of marine losses. The question of canal tolls is discussed in the report at length and with ability. The conclusion reached is that if the registered tonnage be adopted on the basis of toll charges, a vessel of 3,000 tons measurement could be charged two-thirds of 42 cents, or about 28 cents per ton for tolls. The same charges should apply to vessels plying between the Gulf ports and the ports of Europe, and, indeed, to all vessels using the canal, regardless of their nationality or the ports of their arrival and departure. Allowing for somewhat more favorable premises than those adopted in the foregoing discussion, the tolls might, perhaps, be carried as high as 35 to 37 cents per ton of registered tonnage during prosperous seasons, while at other times it might be necessary to drop them to 25 cents. These figures seem to condemn the project to financial failure. If the canal is to cost about \$50,000,000 and \$500,000 per annum for maintenance, and if all the tonnage passing through the straits is diverted to the shorter route at a charge of 28 cents per ton toll, the profits will be less than half of 1% of the original cost.—*Iron Age.*

The electric light burns brightly under water. During the past year the German army used it successfully for submarine operations.

Mining and Scientific Press Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept pace with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice free. Address, **DEWEY & CO.,**

Office MINING AND SCIENTIFIC PRESS AND PACIFIC RAIL PRESS, 202 Sansome Street, S. F.—1880.

Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

NOW READY!

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW on SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Quarto. 234 Illustrations.

By ROBERT GRIMSHAW, Ph. D., M. E.,

Member of the Jury on Wood-working Machinery at Paris Exposition of 1878.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand, ash, Mulay, jig, drag, circular, cylinder and hand Saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other saving operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, swaging, gumming, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 180, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copiously indexed.

Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the price is this date made \$2.50, postage paid.

ROBERT GRIMSHAW,

624, 626 and 628 Market Street, Philadelphia

March 10 1880.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

California Inventors

Should consult DEWEY & CO., AMERICAN AND FOREIGN PATENT SOLICITORS, for obtaining Patents and Caveats. Established in 1880. Their long experience as journalists and large practice as patent attorneys enables them to offer Pacific Coast Inventors far better service than they can obtain elsewhere. Send for free circulars of information. Office of the MINING AND SCIENTIFIC PRESS and PACIFIC RURAL PRESS, No. 202 Sansome St., San Francisco.

Also Water-Proof Leather Belting.

NO. 10 FREMONT ST., near Market, SAN FRANCISCO

A Card from Architects.

The California Architect and
Building Review.

Office, No. 240 Montgomery Street, San Francisco, Cal.

It is with pleasure that we publish the following from prominent Architects in this city:

Believing that a journal of its kind is a necessity on this coast, and judging from what has appeared in the "Quarterly Architectural Review," we are led to believe that the CALIFORNIA ARCHITECT AND BUILDING REVIEW will be worthy of generous support and encouragement. We therefore pledge our cordial sympathies, personally, and hope that the enterprise will receive kindly recognition and liberal support from all Architects and Builders and the public generally. (Signed) David Farquharson, Wright & Sanders, S. H. Williams, Thos. J. Welsh, P. Hume, John Marquis, B. McDougal & Son, Wm. Mooser, Wm. Curlett, Meeker & Banks, W. C. Hoagland, S. & J. Newsum, B. Henrickson

COPP'S

AMERICAN SETTLERS' GUIDE.

Public Land System Explained; How to tell Township and Section Corners; How to Homestead and Pre-empt land; How to Enter land under Timber Culture, Desert, Townsite and other Laws. Sent by mail postpaid for 50 cents.

DEWEY & CO.

202 Sansome St., S. F.

Well Tested Mining Devices.

GRATE BARS—Hydraulic. A saving of about half the usual expense. GROOVED RIFLES—Hydraulic or quartz. Will largely increase the yield of gold. Concentrators No. 1 and 2. Former with machinery. Letter for fine Gold, Sulphur or Black Sand. BRYAN TYSON, Patented. Manufactured by Rankin & Co., Pacific Iron Works.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.

FOR THE WEEK ENDING AUGUST 24th, 1880.

231,554.—HEEL SHANK AND COUNTER SUPPORTER.—Henry Flindt, Albany, Ogn.
231,430.—WINDMILL.—Henry P. Johnson, S. F.
231,443.—BOILER.—Joseph R. Mitchell, S. F.
231,623.—RUDDER.—N. B. Scott, Portland, Ogn.
231,502.—DOOR-KNOS ALARM.—John Simon, Oakland, Cal.

231,505.—STEERING APPARATUS.—A. J. Stevens, Sacramento, Cal.
231,638.—SQUAR MACHINERY.—W. H. Wiester, S. F.
231,617.—GATE.—Wm. Robinson, Bodega, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

CLAMP FOR ROCK DRILLS.—H. Richmann, San Francisco. Patented August 17th, 1880. No. 231,238. This invention relates to certain improvements in that class of devices which are used to support the cylinders of direct-acting engines intended to actuate, by air or steam, a drill or tool for boring rock; and it consists in a novel method of connecting the case or carriage carrying the cylinder to the column, and in an improved clamp for holding it in position on said column.

CHAIR BRACE.—S. P. Sorenson and J. C. Stanton, Rio Vista, Solano county, Cal. Patented August 17, 1880. No. 231,245. The construction of this improved chair brace consists in a peculiar combination of an adjustable side or arm-brace with the leg braces or rods, said arm-brace being provided with a turn-buckle, so that the regulation of the arm-brace also regulates the leg braces, and the parts of the chair are bound more firmly to each other.

EXPLOSION IN A COAL MINE.—A dispatch from Shenandoah, Pa., September 1st, says: This afternoon George Ormrod, Superintendent Kehley, of the Run colliery, and six others descended into the mine for the purpose of putting a door in the main battery, to see what progress the steam which was being injected into the mine was making on the fire in the "breasts." When the opening for the door was nearly completed a fall of earth occurred near the face, causing a concussion of gas, which blew the men in all directions. Simon Gregory was killed, Ormrod had a leg broken, and Joseph F. Jones had an arm broken. All the others were severely burned by steam. Gregory's body has not been recovered, the black damp being so bad that the miners could not venture far in without being overcome by it.

COLLAPSE OF THE WHEAT CORNER.—The recent collapse of the wheat "syndicate" has moved the Springfield Republican to characterize it as an "abominable conspiracy to control the price of the first necessary of life." Thanks to the generous earth, for two months cheap bread has been one of the certainties of the future. That paper says: With an American crop of from 450 to 500 million bushels, one-third at least available for export, a speculator on a basis of 16 million bushels is dealing in small potatoes. Mr. Keene must be reminded of an eloquent question in his favorite work: "Canst thou draw out leviathan with an hook?"

A RAILROAD CONDUCTOR KILLED.—A Tucson dispatch of 1st Sept. says that William Reed, recently promoted to a conductorship on the Southern Pacific Railroad, who was on his first trip last night, fell between two cars while in motion, between Pantano and Mescal. The cars passed over one of his legs and the foot of the other, crushing them in a terrible manner. He was brought to the hospital at this place to-day, where both limbs were amputated. It is thought that he cannot possibly live.

IN MR. HOLMAN HUNT'S picture of "The Flight into Egypt," the donkey from which he painted is stated to be an animal of purest breed, boasting a genealogy of two centuries; while the Virgin is taken from a lovely Jewish maiden living in the neighborhood of Bethlehem. One original feature in the picture will be a procession of infant spirits—those of the murdered innocents. Mr. Hunt has been engaged on this picture for four years, and it will take six months to finish it.

GOLD mining in Virginia is becoming an important industry. The mines of Buckingham, Spottsylvania and other counties are being energetically worked. The county of Montgomery is now developing a promising business in that line.

Is South America Rising or Sinking?

The question whether the South American continent is sinking or not is one on which considerable differences of opinion still exists. Prof. Orton several years ago expressed the belief that the barometric observations of the heights of the principal mountains, which have been continued through more than a hundred years, afforded evidence of a gradual sinking, and this opinion has prevailed extensively. Prof. Agassiz believed that the eastern coast was sinking while the western coast was rising, and Darwin infers, from the discovery of the remains of an ancient civilization on lands that are now too high for the development of human life, that the land is rising. Dr. W. Weiss read a paper before the Berlin Geographical Society at a recent meeting, in which he advanced the theory, founded on a comparison of observations which had been made at the mouths of rivers, that the continent is rising. The Isthmus of Panama seems to be rising, and signs of elevation are apparent on the north coast of the continent. The delta of the Magdalena river has suffered notable changes within recent times. The tertiary highland of Turbaco, which extends from Carthagena to Sabanilla, was once an island in front of the stream, as indicated by the forking of this river. One arm of the river empties toward the west near Carthagena, the other arm forms the present mouth with its branches in the lagoon of Santa Marta; ships formerly sailed into the western arm, which is not now navigable. The closing of this branch is generally ascribed to the luxuriant vegetation, but it is more than probable that other causes were combined with it. A small elevation would be enough to stop the flow of water, and the fact that such an elevation has taken place is shown by the discovery of recent shell-hells in a part of the lagoon. The bay of Santa Marta, with its monotonous sand flats between steep, bald cliffs and island-like uprising knobs, produces the impression of a recently dried sea-bottom. Similar appearances are presented farther east, to such an extent that it was believed in the sixteenth century that the sea had retreated. The region of the lagoon of Maracaybo, and indeed the whole coast of Venezuela, appears to have taken part in a movement of uprising. The existence of the delta of the Orinoco favors the theory of elevation, for, though it can not be held that deltas are not formed except where the ground is rising, it is nevertheless true that elevation is most favorable to their formation. The observations along the coast of British, French and Dutch possessions are contradictory; but as a whole they seem to indicate that the land is gaining on the sea. The character of the changes that are taking place at the mouth of the Amazon is generally supposed to indicate a sinking of the land, but there are circumstances that favor the opposite view. The signs that the upper part of the bed of the river is rising are numerous, and all the phenomena of washing away at the mouth which are generally considered evidences of a depression can be accounted for by supposing that the interior is rising faster than the coast. Indications of a recent elevation may be seen all along the coast from Cape St. Roque to the La Plata, in the hardened shore ridges of Rio Grande do Norte, Parahyba and Pernambuco, the elevated shorelines of Rio Vermiglio, Bahia and Rio Jequitinhonha, the coral reefs of the Abrolhos, the holes of the sea urchin found above the level of the sea near Cape Frio, the new formations near Rio de Janeiro, the deterioration of the harbors of Santa Catarina, Porto Alegre and other places. Darwin proved by the discovery of recent shell-deposits that the region of the La Plata was rising; since then some facts have been adduced pointing to a sinking, but the La Plata affords relations similar to those which have been referred to in the case of the Amazon. A lake in the Straits of Magellan containing marine animals, but situated at a higher level than that of the sea, is cited by Agassiz in proof that a rise of the land has taken place there. On the west coast signs of a sinking appear in the Chonos Archipelago, but they give way to trustworthy evidences of elevation in southern Chile. These continue to Callao and Lima, where a sinking is suddenly indicated. The land at Callao consists of gravel-hills, which may be considered as river and shore formations. Washings away from beneath, assisted by earthquakes, might readily have caused slight local falls, without making it necessary to invoke a sinking of the land. Not enough is known of the coast north of Callao to justify a definite expression of opinion.—*Popular Science Monthly* for September.

HURRICANE IN JAMAICA.—A terrific hurricane passed over the island of Jamaica on the night of Aug. 20th. Thousands of people are homeless. The crops, fruit trees, and farm produce were generally destroyed. Colossal trees were uprooted, and churches were demolished; and the barracks in the city were also destroyed. Three wharves are gone, and eight large and 32 small vessels were wrecked in the harbor. A famine is imminent, and help is required for the starving thousands.

THE RHENISH VINTAGE.—A late dispatch gives this intelligence: The consul of the United States at Cologne, commenting upon the prospects of the vintage of the Rhine and its tributaries the present season, says that it is thought by experienced observers that the vintage will not exceed one-fifth of the average yield.

San Francisco Plating Works.

Mr. E. G. Denniston, of the San Francisco Plating Works, exhibits at the pavilion a case of plated ware, a case of old goods replated and a large silver-plated mining plate. Mr. Denniston is the pioneer plater in this city, doing the work in all its branches—gold, silver and nickel. A specialty at these works has been, for some time, silver-plated amalgamating plates for miners' use. It has been found by experience these plates are very much superior to the ordinary copper ones. Mr. Denniston now supplies them to all the leading mills on this coast. He has on exhibition in this fair the largest silver-plated plate ever prepared. Mr. Denniston is a master artist in this line. His plating works are among the most extensive in this country. He has the largest silver-plating vat in the world, and is prepared to furnish silver plated amalgamating plates for quartz mills on the shortest notice. His nickel and copper-plating vats are the largest on the coast. He has an engine boiler for polishing and an electric machine for facilitating the plating process.

A recent visit to this establishment repaid us, for we saw there one of the largest, most elaborate and elegant specimens of gold plating ever done here or anywhere else. It is a large, ornamental double gate, each section being two feet wide and seven feet high, and finished with a cap of interlacing arches, surmounted with a crown. Underneath this symbol is the monogram of the person whose silent resting place it is destined to adorn. This exquisite piece of workmanship is for the mausoleum of a former well-known citizen, and must take rank among the most noted and beautiful *chef-d'œuvre* of industrial art. The moulding is of brass, rarely designed and finished. In order to do the plating a special vat was made. Part of the design is in dead gold, part bright, the whole being of unique and striking appearance.

POPULAR SCIENCE MONTHLY.—More than any other American magazine, it seems to us, the *Popular Science Monthly* maintains the quality of attractiveness in its well-filled and valuable pages, and we give it cordial welcome to our table. The contents of the September number embrace no less than 13 articles on various subjects of interest, besides editorials, miscellany, notes, etc., all relating to the higher applications of science. The opening article on "Comparative Jurisprudence," by William M. Ivins, will prove both interesting and instructive to the lawyer of critical taste. The Hon. Auberger Herbert's article on "State Education: A Help or Hindrance?" seems to prefer the voluntary system of education, and treats the subject after the manner of Herbert Spencer. The latter does not agree with those writers who, like Macaulay, held "that whoever has the right to hang has the right to educate." A brilliant article on celestial dynamics is Dr. C. B. Waring's, "The Solar System and its Neighbors." The "Legal Prosecution of Animals" is a very curious article, the reading of which will clearly show the degrading stupidities from which science has relieved society. Prof. Preyer's "Psychogenesis in the Human Infant" is an able and interesting essay on mental development in infants, and commends itself especially to intelligent mothers. There is an interesting paper, well illustrated, on "Climbing Plants," by Francis Darwin; and a very delightful one by Prof. Grant Allen on the "Æsthetic Feeling in Birds." "The English Precursors of Newton" is the first installment of a most remarkable chapter in scientific history. The biographical sketch, accompanied with a portrait of the distinguished naturalist, Dr. Joseph Leidy, is pleasant reading. And, finally, there is a rasping article by the editor on "Sewage in College Education." Not the least valuable feature of the *Monthly* is its copious miscellany. It is published by D. Appleton & Co., N. Y., at \$5 a year or 50 cents a single copy.

THE SOUTHERN PACIFIC IN ARIZONA.—The Southern Pacific railroad is fast pushing its work through Arizona. On the 23d of August they had successfully surmounted all the obstacles met in the Dragoon range of mountains, and the builders immediately began to push forward at the liveliest rate for El Paso, over 200 miles distant from the end of the track. It is their intention to accomplish this distance in 100 working days. The expedition of the builders, considering the climate of the country they are working in, is simply wonderful. For example: on the 24th ult., they laid 12,200 ft. of steel rails, on the 25th, 11,600, on the 26th, 12,800, and on the 27th, 12,000. This is extraordinary work. At this rate the company will carry the road to El Paso by Christmas certainly. The road is now completed and in running order 112 mile from Tucson, and is only 25 miles from the boundary line of New Mexico, which will be reached in about 12 days. Since the close of January of this year the company has built and put in perfect order 176 miles of steel-laid road.

LATELY the blueberry plains in Washington county, Maine, were a vast camp ground, 1,000 pickers tenting there,

News in Brief.

SINCE the beginning of the year there have been 140 duels in France.

FIVE cases of supposed yellow fever have appeared on a Mississippi tow boat.

FOUR colored Episcopal ministers are at work in Tennessee among the colored people.

ONE man was killed and three were injured by a collision on the Lake Shore road, Aug. 28th.

It is said that 16 bridesmaids will be one of the features of an October wedding at Trinity Church.

CALVIN SYKES, of Snfield, Conn., refuses to shake hands with any one, and has not done so for years.

FIVE boys riding on the top of a car were struck by a bridge and killed near Lowell, Mass., on Saturday night, Aug. 28th.

THE Mormons began work on their new temple 20 years ago, have expended \$4,000,000 on it, and it is now one-fourth done.

THOMAS SCOTT and Mrs. Heffner, while walking on the track near Mount Carbon, Pa., Aug. 30th, were killed by the fast express.

HORACE DAVIS has accepted an invitation to deliver the annual address before the State Agricultural Society at the State fair.

JAMES BENNETT, a fireman on the Denver and Rio Grande railroad, was murdered by drunken roughs at San Antonio, Col., Aug. 30th.

THIRTEEN steamers of the Dundee whaling fleet had taken up to this 15th of Aug., 105 whales, producing about 1,000 tubs of oil.

It is thought that six passengers and two sailors were lost at the time of the burning of the steamer *Marine City* on Lake Huron.

MR. CONWAY says that Carlyle neither reads nor writes, but lies on a sofa and longs for death. Carlyle will be 82 in December.

DR. W. S. BOW EN has examined 1,820 railroad employees in Rhode Island for color blindness, of whom less than 4% were rejected.

ALLEGED intellectual Boston girls at Swampscott call the beach "Neptune's lawn," and allude to shells as "products of the deep."

AT DALLAS, Texas, August 27th, 3,000 people, women predominating, collected to witness the hanging of Allen Wright, a colored man.

CAPT. SIR LAMONT LORRAINE, well known in this country in connection with the *Virginian* massacre, is to take command of the *Cleopatra*.

C. M. CHASE has been appointed to fill the vacancy on the State Board of Agriculture caused by the resignation of Marcus D. Boruck.

The city of Philadelphia has bought for \$10,000 the marble fountain made by the late Margaret Foley of Boston, and shown at the centennial.

THE authorities of Detroit, Mich., have refused to license a company of hare-legged blondes who sought to exhibit their figures there.

PERE HYACINTHE, Aug. 28th, solemnized the marriage of the Abbe Laine, until recently a priest of the diocese of Mans, with a Madame Wochese.

THE Pope has assented to the proposal that a portion of the Frenob Jesuits should form a society for the propagation of the faith in central Africa.

THE Province of Quebec Mortgage Bank has been founded by the Bank of Paris, with a capital of \$25,000,000, the first issue to be \$5,000,000.

FREDERICK FREY, living with John Chapman at Suffield, Conn., mistook a teaspoonful of arsenic last week for another drug, and died in consequence.

A LEICESTER (Mass.) woman who has felt something crawling about her stomach more or less for 15 years, vomited up a lizard over three inches long the other day.

PROF. SHELDON has been commissioned by the Canadian government to write a report on the advantages and disadvantages of Canada as a place of settlement for English farmers.

Two or three short railroads run out of the city of Mexico for a few miles, and the trains are usually accompanied by a rear guard of soldiers for protection against the brigands.

THE reckless gambling at London clubs has become a scandal, for scarcely a week passes that the quarrels of the alleged gentlemanly gamblers do not extend to the police court.

JOHN RARNHART SHEFFLEY and his wife, Maria Barbara Sheffley, of Limerick square, Montgomery county, Pa., have been married for 71 years. The husband is 89 years old and the wife 88 years old.

MR. JOHN C. HAMILTON, son of Alexander Hamilton, is in vigorous health, despite his 86 years. He made a visit recently to Hartford to view the model of a statue of his father, which is being reproduced in granite.

PROF. TAIT, at a meeting of the Royal Society of Edinburgh, on the 8th of June, sent in a note on the theory of the "15" puzzle, and gave a rule for determining whether a particular arrangement was solvable or not.

REV. DR. THOMAS GALLAUDET, who sailed on Saturday on the White Star steamer *Britannic*, is a delegate to the convention of deaf mutes to be held at Milan next month. He is accompanied by his wife, who is a deaf mute, and by a young lady, also a deaf mute.

PROF. MOMMSEN, whose historical library and manuscripts were burned in Germany, has declined to have a fund raised in England. He says the property was insured for enough to cover its intrinsic value, and money cannot restore it. He is going soon to Italy to renew his copies of ancient Roman inscriptions.

Pocket Mining Atlas,

Containing the principal mining districts in the United States. Compiled from the latest official surveys and the most authentic sources by Edwin Bolitho. Sent, post-paid, on receipt of \$1. Address, Dewey & Co., 202 Sansome St., S. F.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omissions of agents.

Nothing short of Unmistakable Benefits

Conferred upon tens of thousands of sufferers could originate and maintain the reputation which AYER'S SARSAPARILLA enjoys. It is a compound of the best vegetable alteratives, with the Iodides of Potassium and Iron, and is the most effectual of all remedies for scrofulous, mercurial or blood disorders. Uniformly successful and certain in its remedial effects, it produces rapid and complete cures of Scrofula, Sores, Bolls, Humors, Pimples, Eruptions, Skin Diseases and all disorders arising from impurity of the blood. By its invigorating effects it always relieves and often cures Liver Complaints, Female Weaknesses and Irregularities, and is a potent renewer of vitality. For purifying the blood it has no equal. It tones up the system, restores and preserves the health, and imparts vigor and energy. For forty years it has been in extensive use, and is to-day the most available medicine for the suffering sick anywhere.

FOR SALE BY ALL DEALERS.

HOW TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for \$3 per (half-yearly) volume. In cloth and leather binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

INVENTORS, and others interested, will receive Dewey & Co.'s MINING AND SCIENTIFIC PRESS FREE OF CHARGE on application at this office. It contains 42 pages of hints and information about Patents, Patent Laws, Patent Office Regulations, and how to obtain valid patents.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus, terms of subscription, etc., and request that they circulate the copy sent.

J. C. COLMERY is requested to report to this office from Humboldt Co.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

Chew JACKSON'S BEST Sweet Navy Tobacco.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

DIVIDEND NOTICE.

OFFICE OF THE
Napa Con. Quicksilver Mining Company,
SAN FRANCISCO, AUGUST 30th, 1880.

At a meeting of the Board of Directors of the above-named Company, held this day, a Dividend (No. 12) of Ten (10) Cents per share, was declared, payable on WEDNESDAY, the first day of September, 1880, at the office of the Company, Room 16, Academy Building, No. 330 Pine St., San Francisco, California.

WM. W. PARRISH, Secretary.

DIVIDEND NOTICE.

OFFICE OF THE
Standard Consolidated Mining Company,
SAN FRANCISCO, SEPTEMBER 1, 1880.

At a meeting of the Board of Directors of the above-named Company, held this day, Dividend No. 19, of Seventy-Five cents (75) per share was declared, payable on MONDAY, September 13, 1880, at the office in this city, or at the Agency of the Nevada Bank of San Francisco, in New York.

WILLIAM WILLIS, Secretary.

Office—Room No. 29, Nevada Block, No. 300 Montgomery St., San Francisco, Cal.

Gover Mining and Milling Company.—Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.

Notice is hereby given that at a meeting of the Directors held on the Eleventh day of August, 1880, an assessment (No. 43) of 20 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 402 Front street, room 8, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Thirtieth day of September, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Monday, the Eleventh day of October, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

W. O. WILSON, Secretary.
Office—402 Front street, room 8, San Francisco, California.

Techattucup Silver and Gold Mining Co.

Location of principal place of business, San Francisco, California. Location of works, El Dorado canyon, Lincoln Co., Nevada.

Notice is hereby given that at a meeting of the Trustees, held on the 24th day of August A. D. 1880, an assessment (No. 7) of One Dollar per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, No. 237 First street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 30th day of September, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Wednesday, the 20th day of October, A. D. 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

C. F. MOUTRIKOP, Secretary.

Office—No. 237 First street, San Francisco, California.

Cups for Engine, Machine and Shaft Bearings and Loose Pulleys. We furnish the Albany Compound (a solid), \$1 worth of which will last as long as from \$2 to \$10 worth of Oil, with no stop, and with ONE-TWENTIETH the attention required by the best Oil Cups.

If the Cups are not satisfactory, we will receive them back and make no charge.

Cylinder corrosion is not so much owing to impure tallow or oil as to the fact that those animal fats do not maintain their integrity under steam heat, but decompose and set free acids which attack and destroy metal.

The Albany Cylinder Oil does not contain fatty acids—is incapable of being decomposed and does not form insoluble soaps. If it becomes mixed with boiler incrustation it diminishes its tendency to cling to the sides of the boiler, and thus exerts in this respect also a beneficial action.

THE ALBANY Cylinder Oil

The Cheapest and most economical Cylinder Cup. Can be instantly regulated to feed a few drops per minute, and the drops can be counted as they pass through the glass gauge.

Is now in use throughout the world, and we refer to nearly all first-class establishments on this coast for evidence of its efficacy.

Pure Winter Strained Lard Oil

By every vessel from New York.

ALBANY SPINDLE OIL,

Genuine West Virginia Lubricating Oil,

SIGNAL OIL for outside lights of vessels, etc.

The Albany Lubricating Compound and Cups, the Albany Spindle Oil, etc., can only be gotten from us or our agents. Send for catalogues.

TATUM & BOWEN,

DEWEY & CO.'S

Scientific Press

Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with
Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when ad-
visable.

STEAM LAUNCHES, Barges and Steam Tugs con-
structed with reference to the Trade in which they are
to be employed. Speed, tonnage and draft of water
guaranteed.

STEAM BOILERS. Particular attention given to
the quality of the material and workmanship, and none
but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING
MACHINERY made after the most approved plans.
Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size
made in suitable lengths for connecting together,
sheets rolled, punched, and packed for shipment ready
to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and
Water Pipe made by this establishment, riveted by
Hydraulic Riveting Machinery, that quality of work
being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam
Winches, Air and Circulating Pumps, made after the
most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City
Water Works purposes, built with the celebrated Davy
Valve Motion, superior to any other Pump.

New Book on the Comstock.

The attention of MINING ENGINEERS and EXPERTS
is called to the new work by JOHN A. CHURCH, E. M. Ph.
D., on "The Comstock Lode, its Formation and History." This
very exhaustive treatise on this famous lode is fully
illustrated with diagrams and colored charts showing sec-
tions, ore bodies, etc., and will be of great interest and per-
manent value for reference. DEWEY & CO., Publishers of
the MINING AND SCIENTIFIC PRESS, are sole agents for the
sale of the work. Mr. E. M. SLEATOR will act as their
agent, and call on Mining Engineers and those interested in
the great lode in this city with a copy of the book for their
inspection.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Small Sizes made in Sections not to Exceed 300 lbs.

Hoisting and Pumping Machinery.

STEIGER & KERR'S CONTINUOUS DISCHARGE AND GRINDING PAN.

This pan is designed to receive ore direct from a rock breaker, and reduce it to the fineness necessary for amalgamation, thus taking the place of the ordinary stamp battery. The cost of this Mill places it within the reach of all; and one point of advantage not to be overlooked is the fact that the cost of erection, which adds so much to the expense of the stamp mill, after it leaves the foundry is, in this case, reduced to a fraction, as the Mill is complete in itself, and requires no expensive foundations, bed logs, battery frames, etc., but can be placed in position in a few hours after it arrives on the ground, without the aid of skilled labor. This simple arrangement, durable as it is simple, is a most important improvement in the working of gold ores, as it enables parties to construct and erect a mill at half the cost of a stamp mill, and with a great saving of time, and size of mill building. Each pan is capable of reducing 10 tons of average ore in 24 hours, the ore being first broken in a rock breaker, small enough to go through a half-inch screen. There is an important point in the action of this Mill, to which we desire to call the attention of miners and millmen. We allude to the grinding and scouring action on the gold before it is discharged. The value of this point cannot be over estimated, and it is not necessary to do more than mention the fact, as it will be at once recognized by all competent millmen who examine the pan in operation, and especially by those who have had to deal with tarnished or rusty gold, as it is commonly called, and which is often encountered in our mines, and which is such a cause of loss. The pan of feeding is the same as in the stamp mill, either an ore feeder or hand feeding being adopted, as may be desired. Parties interested in mining and mills can see the Pan in operation by calling at the OCCIDENTAL FOUNDRY, STEIGER & KERR, 137 First St., S. F.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

A New Submarine Torpedo.

The mysterious torpedo, about which so much has been said and written, which is being experimented with at Willett's Point, is entirely different from any other floating torpedo known in this country. The torpedo is the design of a Mr. Sims. It is thus described by the *American Ship*: This torpedo is of the ordinary cylindrical cigar-shaped hull, with fins lines, and is divided into three apartments, the forward one, or magazine, being filled with an explosive compound, which is fired by electricity. The middle compartment contains a roll of fine telegraphic wire about 1½ miles long, which is played out through an aperture in the bottom, while in the after section is located the propelling engine, which drives a screw propeller at a velocity of, so far as tested, 12 miles an hour. The motive power is electricity, conveyed to the torpedo through this roll of wire referred to; and through this wire connection control is exercised over the screw and rudder, as well as the firing of the magazine. From the torpedo rises two stanchions, placed on each outer section, which connect with a light float, V-shaped on the sides and convex on the top. The torpedo proper is raised or lowered by means of the stanchions and float, so that any class of vessel with an overhang or partly armored can be reached by the impinging end of the torpedo, and the explosive power exerted at any depth of water desired. As seen in the water, nothing is seen but the crest of the float with the heads of the stanchions, on which are placed tiny flags, which serve to show the operator the direction and speed of the torpedo machine, and enable him to turn the proper switch and fire the charge of dynamite or other compound. Thus far the experiments have proved very successful. The electric battery for working this torpedo from forts is kept within the fort or placed in a bomb-proof near the scene of operations. It can also be operated from the deck of a cruising vessel or launch.

THE FUTURE LUMBER SUPPLY.—What are the lumbermen of the Pacific coast doing to replace the forests they destroy? This is a serious matter, and it ought to be looked squarely in the face. It is attracting the attention of ship builders and other lumber interests on the Atlantic side, and it should not be neglected on the Pacific where the lumber industry is assuming vast proportions. In relation to this business, the *American Ship* thinks that the Lumbermen's Association should consider the matter and endeavor, through the action of its members, to secure protection for the timber lands so that the trees shall be thinned out rather than destroyed, and given an opportunity to make fresh growths from year to year. That journal says: Some legislation may be needed in the public interest for the protection of the forests against the cupidity of men, anxious only about present profits, and the Lumbermen's Association ought to be able to suggest measures that will be fair to all interests. There is scarcely a nation in Europe that does not to-day regret its neglect to provide in time for forest culture, though nearly all now have laws on the subject. The existing laws in this country are really applicable only in the far Western States, where there are public lands which might be worth obtaining for forest culture. In the States now most in need of growing forests, there is very little tree planting, but the waste goes on at a great rate.

NATURAL SILVER PLATING.—A singular instance of natural silver-plating is reported by the *Register-Call* as occurring in the Lord of Lorne mine, American Flat, Gilpin county, Col. The sides next to the vein and the hanging wall are covered with a thin coating of native silver as smooth as glass. The vein itself is narrow, and is prospected by means of a tunnel. The superintendent of the mine says this curious feature of the inclosing walls is observable so far as the tunnel has followed the vein. The ore is friable and easily mined, and discloses both chlorides and sulphurets, but does not assay highly. The filmy coating of silver on the walls was apparently condensed and deposited there under tremendous pressure, for it has a smooth and burnished appearance.

Petroleum as Fuel.

It seems that petroleum is successfully used as fuel in generating steam. A special correspondent of the London *Daily News* gives a description of the mail steamer *Cesarewitch*, on which the application of petroleum has been made. The vessel is of English build, and is the swiftest mail steamer on the Caspian sea, being only surpassed in speed by the *Nar Eddin Shah* war steamer. That paper says: To convey it from the Baltic to the Caspian, it was necessary that it should traverse the whole of the Neva ship canal, and afterwards descend the Volga to Astrakan. On the Neva canal are 54 locks, and the *Cesarewitch's* length was too great to allow of her entering them. Her present chief engineer, Mr. Vine, an Englishman, cut her into two pieces amidships, and filling up the open extremities with iron bulkheads, floated her in this guise through the canal. At Astrakan the same gentleman put her together again, and has remained ever since in charge of her machinery. Her boilers are heated by petroleum refuse instead of coal, a system which effects an enormous saving of expense and labor, the heating apparatus being as thoroughly under control as a gas jet, and requiring but one man to manipulate it. It consists of two tubes, about an inch in diameter, terminating at the same point in a small ohlong

THE FRUE CONCENTRATOR.

brass box. Through one of these tubes the black residual naphtha (*astaki*) drops slowly, being blown into spray by a jet of steam from the boiler, conveyed through the second tube. This spray, when ignited, forms a great sheet of flame, which is projected into the hollow of the boiler. It has the immense advantage of requiring no stoking, as no ashes are produced; and by turning down the flame to the required degree, the steam can always be kept up to the pressure required for immediate starting without the tedious and more or less wasteful process of "hanking" the fires. An arrangement like this is invaluable for cruisers lying off any enemy's port, and requiring to hold their steam in readiness. It is intended to apply the same system of heating to the locomotives on the Tiflis Baku railway, when completed; and it will, doubtless, play an important part in the steam communications destined at no distant period to traverse the Steppes to Khiva and Samarcand.

Too ENERGETIC.—Late advices from Santa Fe state that at the town of Las Placitas, the new mining camp, distant some 40 miles from Santa Fe, where gold was discovered in the streets, the indignant inhabitants drove the discoverer, one Jesse Martin, out of the place. It appears that the energetic prospectors, of whom there was a large influx, attacked not only the streets, but the foundations of houses, and sunk shafts in the cellars. They were far too energetic for the easy-going Mexicans.

BODIE PLACERS.—The *Standard-News* says very little placer mining is now going on on the eastern slope of Bodie ridge or on the flat beyond, but that nearly all the ground in that locality has been taken up; and when the Red Cloud, Bodie-Mono and Dudley begin to discharge heavy streams of water over the eastern slope there is no doubt that large quantities of gold will be extracted.

The Frue Concentrator.

We give an engraving herewith of one of the most successful of the mining appliances used on this coast. It is the Frue ore concentrator or vanning machine, and is on exhibition in the Mechanics' fair, being a prominent feature in the machinery department.

This machine has been described as an improvement on Brunton's revolving belt, but really had its origin in a machine much more resembling the old California "cradle." The employment of a revolving belt, either plain or with riffles or hucks, as a carrier for various materials, is of very old date; but the application of a lateral shaking motion to such a belt—a motion closely resembling that given to a shovel in vanning by hand—is a novelty, and constitutes the essential element of the success of this machine. A revolving belt of canvas, with a lateral or end blow, has been used in Germany and England, and also in the States; and though pretty good results were obtained with it, the difficulty of making the belts last proved too great. The side shake is as great an improvement over the blow, as the perfect rubber belt, with permanent high flanges, is superior to the rough, costly, short-lived canvas belt.

For localities where water is scarce, the Frue has the advantage over any other concentrator, that the amount of water required is very small.

For one machine one-half inch of water, miners' measure, or six and one-eighth gallons a minute, is as large an amount as is ever needed on any material; while on some ores three gallons are sufficient, and by returning the water from the settled tailings, one-half gallon will keep up the loss. The hoiler for a five-stamp battery crushing daily from 10 to 12 tons of ore with two concentrators, calls for one gallon of water a minute; hence, in places where water is extremely scarce, two gallons a minute can supply five stamps, two Frue ore concentrators and the hoiler.

The capacity of each machine is from six to eight tons in 24 hours. The power required to drive them is not over one-half horse power per machine. The labor required is very small—one man on a watch can attend to 16 machines. The wear and tear is merely nominal; the belt will last for years, and any part of the machine can be replaced with a duplicate which will be its exact counterpart. The weight of each machine boxed ready for shipment is 2,200 lbs.; no part weighs over 250 lbs. The price of each machine is \$750, U. S. gold coin, at the works in San Francisco. Orders can generally be filled on four days' notice.

These machines are now in successful operation in many of the mining districts of California and Arizona, Colorado and Montana, and elsewhere; and numerous testimonials prove their perfect work. They have been especially useful in working the gold sands of our ocean beaches. The agents, Adams & Carter, Room 7, 109 California St., will give further information to those desiring it.

In Granite Basin, Plumas county, can be seen a curiosity in the shape of an old quartz mill, which at one time was owned by Mexicans, and which, it is said, was brought from England. It is entirely of wood, and would provoke a smile in these days of improved machinery.

A Volcano Rising from a Lake.

M. de Lessps has communicated some interesting papers on the extraordinary phenomena which accompanied the earthquakes of January last in the republic of San Salvador, to which the French journals add accounts furnished by the consul of the republic and the French consul in Guatemala. The shocks which, although of considerable strength, were not violent enough to do harm to houses, seemed to proceed from a center in the Lake of Bopango or Cojuteque. The waters of this lake having fallen from an extraordinary level to which they had risen before the shocks began, a small island with three peaks appeared to be rising from the center of the lake. One of the peaks reached a height of about 90 feet above the water, and sent forth a column of smoke and flames of considerable height. An attempt was made to approach the island in a boat, but the waters in contact with the hot rock were boiling, and gave out great jets of vapor. The water around the volcano continued to boil for some time after the eruption was over and indicated a temperature of 100° at the edges of the lake. The fish were cooked and rose to the surface, and with them many shells and aquatic animals. The lake is in the line of the volcanoes of Central America, where volcanic cones seem to alternate with lakes, and itself occupies the place of an ancient volcano. Its water is brackish, bitter and almost slimy, and has at times given out bubbles of sulphuretted gas. The rise of the water preceding the eruption agrees curiously with an ancient tradition that earthquakes may be expected whenever the level of the lake is elevated. So fully was this believed that the people were formerly accustomed to dig channels to carry off the superfluous waters; and while they did this they had no earthquakes. These facts have a bearing upon the theory that earthquakes and volcanic phenomena are largely due to the action of water.—*Popular Science Monthly* for September.

IMPROVED LOCOMOTIVES.—The little tank engines which daily go puffing overhead through the street of New York (on the elevated railways), says the *Railway World*, have given such satisfactory performances that plans have been prepared for building others of the type with 4, 6, 8 and even 12 driving-wheels, and calculated for the heaviest work. The advantage claimed for them is, that in proportion to their weight they show large tractive power. And in general it may be said that there is a noticeable tendency to increase the size not only of engines, but of cars as well. Freight cars of 20 tons are supplanting those of 12 tons, and the eight-wheel locomotive, which has been favored for freight service, is being replaced by those of the "Mogul" and the "Consolidation" types. They have been deemed objectionable as wearing hard on the tracks; but as they pull larger trains, and so reduce the number of trains necessary for a given service, the objection, to a considerable extent, nullifies itself. And, moreover, they largely lessen the wages and fuel accounts. And there are rumors of a successful oil-burning locomotive. We took the idea of the locomotive from England, but we have worked over it with originality and independence of authority and tradition, until we have developed a distinctly American type of engine, which, to those knowing how to rightly appreciate and interpret it, is expressive of much that is characteristic in our national life.

MINERAL TANNERIES.—The *Frankfort Patent Gazette* says that mineral tanneries are making great progress on the continent. Recently a model tannery, according to Heinszerling's process, has been erected at Glasgow. A company has been formed in Belgium for the introduction of the process; and it is in operation at Jenappe. The *Gazette* says the process requires no change in the plant of existing tanneries. The new Belgium company has secured the exclusive right to use the process in France, but under the condition that it shall expend, within the period of three years, not less than 4,000,000 francs in the erection of model tanneries. One of these tanneries is also in course of construction at Bilbao, in Spain.

METEOROLOGICAL.

Mountain Lakes of the Sierra Nevada.

(By PROF. JOHN LE CORTE.)

Hundreds of little Alpine lakes, with their clear, deep, cold, emerald waters, are embosomed among the crags of the Sierra Nevada mountains. Their origin may be traced to the more powerful actions of glacial agencies in past times; in some cases, gorges dammed up by ancient moraines. The streams that now supply these "Gems of the Sierra" are born in the cold, gloomy solitudes of the upper mountain region, amid perpetual snow banks. Many of these charming lakes are nestled in the least explored portions of the "High Sierra," and have not been mapped or described; nay, some of them have as yet no designating names. They are the reservoirs of melting snows, and some of them—as those near the headwaters of the Yuba—are the sources of summer supply for hundreds of miles of mining ditches. Hence, the existing condition of our topographical knowledge of these wild and imperfectly explored mountain fastnesses renders it impossible to furnish anything like a complete catalogue of the mountain lakes of the Sierra Nevada. The following table embraces some of the more conspicuous lakes embosomed among the crags of that portion of the Sierra Nevada extending from Lassen's Peak (lat. 40° 30') in the north, to Mt. Brewer (lat. 36° 30') in the south. With the exception of Tahoe, most of them are comparatively small:

Mountain Lakes of the Sierra Nevada.

NAME.	Max. Length in Miles.	Max. Width in Miles.	Approx. Area in Sq. Miles.	Height of Surface above Sea Level in Feet.	Height of Bottom above Sea Level in Feet.
Gold.....	4	2	90	6,814
Truckee.....	3	2	65
Eureka.....	2	2	180
Meadow.....	2	2	5,064
Donner.....	2	2	5,000
Washoe.....	2	2	5,000
Tahoe.....	21 1/2	12	192	6,247	1,645, 4,002
Tenaya.....	1	1

These Alpine lakes, with their clear, fresh, snow-fed waters, surrounded by lofty snow-clad peaks, whose slopes are covered with magnificent groves of pine and fir, constitute the most attractive feature in the lesser summit valleys of the Sierra Nevada. The charmingly picturesque character which they impart to the wild and rugged scenery of these mountains has not been overlooked by tourists, poets and artists. But the inaccessibility of most of these "emerald gems" has prevented them from receiving that notice which their exquisite beauties deserve. As civilization penetrates into these mountain retreats, they will become more accessible, and consequently better appreciated by cultivated visitors. The most extensive, as well as the most celebrated, of these bodies of fresh water is Lake Tahoe. This lake deserves more extended notice:

Lake Bigler, or Lake Tahoe.

Situation.—Lake Tahoe, otherwise called Lake Bigler, the largest and most remarkable of the mountain lakes of the Sierra Nevada, occupies an elevated valley at a point where this mountain system divides into two ranges. It is, as it were, engulfed between two lofty and nearly parallel ridges, one lying to the east and the other to the west. As the crest of the principal range of the Sierra runs near the western margin of this lake, this valley is thrown on the eastern slope of this great mountain system. The boundary line between the States of California and Nevada makes an angle of about 131° in this lake, near its southern extremity, precisely at the intersection of the 39th parallel of north latitude with the 120th meridian west from Greenwich. Inasmuch as north of this angle this boundary line follows the 120th meridian, which traverses the lake longitudinally from two to four miles from its eastern shore-line, it follows that more than two-thirds of its area falls within the jurisdiction of California, the remaining third being within the boundary of Nevada. It is only within a comparatively recent period that the geographical co-ordinates of this lake have been accurately determined.

Dimensions.—The greatest dimension of this lake deviates but slightly from a meridian line. Its maximum length is about 21.6 miles, and its greatest width is about 12 miles. In consequence of the irregularity of its outline, it is difficult to estimate its exact area; but it cannot deviate much from 192 to 195 square miles.

Altitude.—The railroad surveys indicate that the elevation of the surface of its waters above the level of the ocean is about 6,247 ft.

Drainage Basin.—Its drainage basin, including in this its own area, is estimated to be about 500 square miles. Probably more than 100 affluents of various capacities—deriving their waters from the amphitheater of snow-clad mountains which rise on all sides from 3,000 to 4,000 ft. above its surface—contribute their quota to supply this lake. The largest of these affluents is the Upper Truckee river, which falls into its southern extremity.

Outlet.—The only outlet to the lake is the Truckee river, which carries the surplus waters from a point on its northwestern shore out

through a magnificent gorge; thence northeast through the arid plains of Nevada into Pyramid lake. This river, in its tortuous course, runs a distance of over 100 miles, and for about 70 miles (from Truckee to Wadsworth) the Central Pacific railroad follows its windings. According to the railroad surveys this river makes the following descents:

	Distance	Fall.	Fall per Mile.
Tahoe to Truckee.....	14 miles	428 ft.	30 1/2 ft.
Truckee to Reno.....	34 "	1322 "	39 "
Reno to Wadsworth.....	35 "	420 "	12 "
Wadsworth to Pyramid lake.....	18 "	187 "	10 "
Tahoe to Pyramid lake.....	101 "	2367 "	23 1/2 "

Discovery.—There is little doubt but that this is the lake of which the Indians informed John C. Fremont of on the 15th of January, 1844, when he was encamped near the southern extremity of Pyramid lake, at the mouth of Salmon, Trout or Truckee rivers, for he says, "they (the Indians) made on the ground a drawing of the river which they represented as issuing from another lake in the mountains, three or four days distant, in a direction little west of south, beyond which they drew a mountain, and further still two rivers, on one of which they told us that people like ourselves traveled." (Vide Report of exploring expedition to Oregon and north California in years 1843-4. Doc. No. 166, p. 219). Afterwards, when crossing the Sierra Nevada near Carson pass, Fremont seems to have caught a glimpse of this lake, but deceived by the great height of the mountains on the east, he erroneously laid it down on the western slope of this great range, at the head of the south fork of the American river. It is evident, therefore, that the Indians had at that time a more accurate idea of the mountain topography than the exploring party. On Fremont's map the lake is laid down tolerably correctly as to latitude, but is misplaced towards the west about one-fourth of a degree in longitude, thus throwing it on the western slope of the Sierra Nevada and making the head branches of the American river its outlets.

Name of Lake.

Few natural features of our country have enjoyed a greater diversity of appellations than this remarkable body of water. On Fremont's map this lake is called Mountain lake, but on the general map of the explorations, by Charles Preuss, it is named Lake Bonpland, in honor of Humboldt's companion. Under one of these names it appears, in its dislocated position, on all the maps published between 1844 and 1853.

About the year 1850, after California began to be settled in its mountain districts, several "Indian expeditions" were organized by the military authorities of the State. It seems probable that this lake was first named Bigler by one of these "parties of discovery" (probably in 1851) from "Hangtown" (now Placerville), in honor of Gov. John Bigler. Under the name of Lake Bigler it was first delineated in its trans-mountain position on the official map of the State of California, compiled by Surveyor-General Wm. M. Eddy, and published in 1853; and thus the name became for a time established. From 1851 to 1863 this name seems to have been generally recognized, for it is so designated on the maps and charts of the United States prepared at Washington. About the year 1862 the first mutterings of discontent in relation to the name by which this lake had been recently characterized came from the citizens of California. On two occasions it has been brought under the notice of the Legislature of this State. During the 15th session (1862) of the Legislature of California, Assemblyman Benton introduced a bill to change the name of "Lake Bigler." The bill was rejected. The friends of Gov. Bigler did not hesitate to ascribe the desire to change the name of this lake to the inspiration of partisan animosity intensified among the political opponents of the Ex-Governor by the state of feelings engendered during the progress of the civil war.

During the session of the Legislature of California for 1869-70, an act was passed to legalize the name of "Lake Bigler" (Vide "Statutes of California," 1869-70, p. 64.) Notwithstanding this statutory enactment, for the past ten years there has been a very strong tendency in the popular mind to call this lake by the name of Tahoe.

On the map of California and Nevada published in 1874 it is still put down as Lake Bigler, but on the map of the same two States published in 1876 it has the double designation of Lake Bigler or Tahoe lake. At the present time this beautiful body of water seems to have entirely lost its gubernatorial appellation, for it is now almost universally designated Lake Tahoe. It is so named on the "Centennial map of the United States," compiled at the "General Land Office," at Washington, and likewise on the "map of California" contained in the ninth edition of the "Encyclopedia Britannica, Article California." Moreover, it is designated Lake Tahoe in the reports and maps of the Board of Commissioners of Irrigation, published in 1874, as well as in those of the "Water Supply of San Francisco," published in 1877. The cause of this change of name can hardly be sought exclusively in the waning popularity of the worthy Ex-Governor, but rather in the following considerations: 1st. In the strong tendency of the American people to retain the old Indian names whenever they can be ascertained; 2d, in the instinctive aversion in the popular mind to the perpetuation of names of political aspirants, by attaching them to conspicuous natural features of our country; and 3d, in the fact that the

State of Nevada designated its portion of said lake by the Indian name.

Meaning of Tahoe.

The meaning of the word Tahoe is by no means certain. It is usually said to be a Washoe Indian word, meaning "Big Water;" according to others, "Elevated Water;" others, "Deep Water;" and others, "Fish Lake." Whatever may be the meaning of this name, there can be no question but that the Washoe Indians designated this remarkable body of water by some characteristic name long before the earliest pioneers of civilization penetrated into its secluded mountain recess.

Physical Studies of Lake Tahoe.

During the summer of 1873, the writer embraced the opportunity afforded by a six weeks sojourn on the shores of this lake, to undertake some physical studies in relation to this largest of the "Gems of the Sierra." Furnished with a good sounding-line and a self registering thermometer, he was enabled to secure some interesting and trustworthy physical results in regard to this beautiful lake.

(1) **Depth.**—It is well known that considerable diversity of opinion has prevailed in relation to the actual depth of this lake. Sensational news-mongers have unhesitatingly asserted that in some portions, it is absolutely fathomless. It is needless to say that actual soundings served to dispel or rectify this popular impression. The soundings indicate that there is a deep subaqueous channel traversing the whole lake in its greatest dimensions, or south and north.

Beginning at the south end, near the "Lake House" and advancing along the long axis of the lake directly north towards the "Hot Springs" at the northern end, a distance of about 18 miles, we have the following depths:

Station.	Depth in Feet.	Depth in Meters.
1	900	274.32
2	1,385	422.14
3	1,495	455.67
4	1,500	457.19
5	1,500	457.19
6	1,540	469.33
7	1,504	458.41
8	1,600	487.67
9	1,640	499.50
10	1,045	318.39

These figures show that this lake exceeds in depth the deepest of the Swiss lakes, (the lake of Geneva,) which has a maximum depth of 334 meters.

On the Italian side of the Alps, however, lakes Maggiore and Como, are said to have depths respectively of 796.43 and 586.73 meters: These two lakes are so little elevated above the sea that their bottoms are depressed 587 and 374 meters below the level of the Mediterranean.

Systematic soundings such as would be required to furnish contour sections of the bed of the lake along various lines could not be executed in row-boat excursions. The time of the small steamers which navigated the lake could not be controlled for such purely scientific purposes. Operations in small boats could be carried on only during calm weather and it required from 30 to 40 minutes to execute a single sounding of 1,500 ft.

THE FAMOUS HORN SILVER MINE.—This famous silver mine, located at Frisco, Beaver county, Utah Territory, and about 225 miles south of Salt Lake City, is described by an expert as the greatest ore deposit he has ever seen. We gather these details from his description of the mine: The mine is opened to a depth of 315 ft., and horizontally for a distance of 350 ft., and at several points the lode has been crossed to each wall, and exposed an ore body 50 ft. in width, the entire crevice being pay ore. There are three kinds of ore in the mine, each kind being separated by a clearly defined line of demarcation. The largest mass is sulphate of lead, carrying about 66 ounces of silver per ton and 45% lead, and occupying three-fourths of the crevice. This body lies on the foot-wall and is called by the miners the smelting ore. The body next to the sulphate is about 17 ft. wide and worth 87 ounces in silver and a small per cent. in lead, it being known as the leaching ore. In color it varies from reddish brown to nearly white, it being light in weight, and in some respects resembles chalk. It contains granular silica, an uncommon form for that mineral, which gives it a mottled appearance. Analysis shows that it contains 47% silica. On the hanging wall is a body of heavy spar that is sprinkled through with spots of ruby, brittle silver and chloride of silver, this body being the richest of the three, the average product showing it to contain 100 ounces of silver per ton, and with a trace of lead. The lode is a contact vein with a foot-wall composed of dolomitic limestone, that in places is changed to marble and a hanging wall of trachyte. It is the only contact vein that has been found in the district, the other veins being either wholly in limestone or granite.

The Carlisle M. Co. of Meadow Lake district have completed a crushing of 30 tons of ore. In the method adopted, the ores are exposed to the action of the air for some time, crushed wet, roasted and amalgamated slowly. The treatment is not a secret, neither is it patented.

A SYNDICATE of capitalists have organized under the French laws for owning, operating and dealing in American mines.

Interesting Facts About Iceland.

[Popular Science Monthly, from a Lecture by Mr. C. G. W. Lock, before the British Society of Arts.]

Concerning Iceland, Mr. Lock stated that the island, so far from being small, as it is erroneously called, is considerably larger than Ireland or Ceylon. Its situation is such that its whole northern coast is shut in nearly every year by the descent of masses of ice from the north. The southern and western shores are affected by ice in very exceptional instances only. The country is essentially volcanic and mountainous; but Hecla, which monopolizes the geographical knowledge of most students on the subject, does not possess a single characteristic to place it above its fellows. The whole central plateau is a wild waste of lava and volcanic sand, and the only habitable parts of the island are a narrow fringe of coast-land and a few of the larger river valleys. The great ridge of ice-clad hills, stretching across the island, acts as a refrigerator to the moisture-laden winds from the southwest, and produces two distinct climates: the northern, generally dry; and the southern, generally wet, and more temperate than the other. The fact that colonists from Great Britain participated in the settlement of Iceland more than a thousand years ago is attested by the identity of many words that are used by the people with British words. Ponies are the chief animal product of the Island. From them the stocks of the "Black Country" of England are recruited. The sheep furnish a fine mutton, and a wool which is made up into excellent fabrics at home, or is exported. Profitable trades are driven in skins, catgut, fox-fur and eider-down; the cod-fisheries are very important, and considerable trade is carried on in cod-liver oil and shark-oil. The salmon-fishery has been shamefully abused by the excessive employment of barbarous methods of taking the fish. It, however, is the one great attraction the island offers to sportsmen; and more profit might be gained, directly and indirectly, by letting out the streams, as in Norway, to English fly-fishers, than by contracting with fish-curers. The island was at one time well wooded, and supplied itself largely, if not entirely, with cereals, but the climate has deteriorated and the soil became sterile in consequence of the cutting away of the trees, and every grain of corn is now imported from Denmark. The principal mineral product is sulphur, which is deposited in a very finely divided state around the volcanic vents by the vapors issuing through them. It is the custom to describe the sulphur mines of Sicily and the sulphur mines of Iceland as somewhat similar, but for all practical considerations they are as distinct as a coal-seam and a forest. The Sicilian mines consist of deposits formed in past geological ages, now lying at great depths, and utterly devoid of reproductive power; the Icelandic beds are the work of to-day, lie on the very surface of the ground, and live and grow with unabated energy, replacing the deposit as fast as it is removed. The area comprised in the Icelandic sulphur districts collectively amounts to, perhaps, a dozen square miles. The sulphur forms a layer of varying thickness, covered by an earthy crust and underlaid by clays containing sulphur mixed with various acids and salts, and is invariably wet, in consequence of the steam condensed within it. The crystals are almost absolutely pure, but impurities are mechanically mixed with them. Other mineral products are gold and silver, which are found in minute quantities, Iceland-spar, pure specimens of which are valued for optical instruments and cabinets, coarse chalcodones and zeolites, lignite, basalt and volcanic products. The manufacturing industry of the country is confined to woolen fabrics, socks and stockings, gloves and a home-spun cloth, which are excellent.

THE LAW OF MUTUAL HELP.—At the Congress of Russian Naturalists, held in January last, Prof. Kessler delivered an address on the law of mutual help, which, he urged, was entitled to a place by the side of Darwin's law of the struggle for existence. Having given a brief sketch of the theory of the struggle for existence, Prof. Kessler remarked that it did not play the only part in organic development. By the operation of the reproductive instinct, there was developed in the different animal races a strong inclination for a closer association of the sexes, as well among individuals as in the whole group, under which the members of a society, of the whole species or family to which they belonged, were impelled to assist each other in the struggle for existence. He had observed numerous instances in which, after the death of the male, the female died, and conversely, or parents with the greatest self-denial sacrificed themselves for the protection of their young. All such examples showed that the reproductive instinct bound groups of related animals to each other through the law he had enunciated. The principle was not limited to sexual association, but was exhibited wherever mutual help appeared to be necessary. As an example, the case was cited of a group of beetles which would combine their forces with severe exertion to drag away a dead mouse. Further, ants and bees illustrate the operation of the law in a high degree. The principle is developed with especial prominence in mankind. Only by the most powerful co-operation could men have succeeded in reaching the degree of civilization which the race has attained.—*Popular Science Monthly.*

MECHANICAL PROGRESS.

Steel for Boilers.

The failure of the steel boilers of the *Livadia* has naturally caused much comment, and while the facts which underlie the case have not yet come before the public, some hints have been thrown out which ought to serve as a warning to thoughtful manufacturers and consumers. As Dr. Siemens, speaking on the subject before a recent meeting, forcibly puts it: "Unfortunately the demou cheapness has settled on the steel trade."

Coming from such a source and at this time, his words sound a warning which ought not to be disregarded. Although in this country the use of steel for general purposes is not by far as extended as it is in England, Americans should observe every phase of progress there closely. The active and untiring advocacy of steel by well-known engineers has borne fruit in the last four years, and there is not one branch of the constructive trades which has not devoted much and careful attention to it. The examination of the product of modern metallurgy proved satisfactory in almost all cases, the only objection raised being that of the price. Nothing would appear more natural on the part of steel makers than an attempt to lower the cost, but nothing is so likely to retard progress than such efforts if made at a sacrifice of quality. There can be no doubt that the aim of steel makers is ultimately to effect in other branches that which they have succeeded in doing in the rail trade—making a better article at the same or at a price little larger than that asked for the product of older processes. How rapidly this period will be reached depends upon the prudence and tact of the makers themselves. By forcing the development of a trade which is naturally of slow growth, much is lost and but little can be gained. The great task of educating consumers requires time. A knowledge of the material, as well as of the methods of overcoming dangers and averting failures, cannot be acquired in a few years. When it is thoroughly understood how to manufacture high grade mild steels, and how to work them in their subsequent use, the step to the introduction of the more ordinary grades will be an easy and a safe one. That period has not yet come, and the action of Dr. Siemens, in protesting against any premature efforts to bring about the age of cheap steel, is well calculated to serve the best interests of all concerned. As yet, American steel makers have been extremely cautious, and are rapidly earning for their product an excellent reputation. We trust that this policy will be strictly adhered to in the future, and that they will not succumb to the temptation of abating their vigilance in the selection of raw materials for the sake of getting for the moment increased profits. We do not wish to urge that the cry for cheap steel be disregarded, but every effort should be made to convince consumers that as yet high grades are safest and best, and that their policy ought to be to exclude, by rigid and comprehensive tests, any deficient or untrustworthy material.—*Iron Age*.

CHAIN FIRE-GRATE BARS.—A boiler in the Birmingham (Eng.) corporation water works, according to *The Engineer*, has for several months been fitted up with the arrangement of a common chain fire-grates, invented by Mr. W. Welch of Ashton Village, near Birmingham. The furnace is six ft. by three and a half, and when the notice was made, had been at work about four months, continuously, night and day, with the most satisfactory results. The chain is arranged to run over drums, like an endless apron; is kept constantly in motion, the feed being made automatically at the front of the grate, precisely as the batteries are fed at many of the quartz mills in this State. When the chain reaches the front, on its under passage, by an additional roller it is made to drop and pass through a trough of water. This may be used or dispensed with as experience may dictate. It is stated that a complete combustion of the fuel is effected without smoke. Thus far the grate has given no trouble, and is as perfect as when first put in. It is claimed for the arrangement that the large and completely distributed air-space area permits the maintenance of a clear, smokeless fire without a heavy draft, perfect combustion being secured. Clinkers do not adhere to the chains.

A NOVEL HORSESHOE.—A manufacturer in Berlin, Germany, is turning out a novel horseshoe made of malleable iron. It is not made solid, but has a deep and wide groove, into which tarred hemp rope is so firmly wedged that it cannot be withdrawn. It is so thick that it protrudes considerably beyond the rim of the malleable shoe. It is stated that the lightness of this horseshoe has gained for it considerable favor in Berlin.

A MACHINE, by which 600 pails can be turned out daily, the sides of each pail being made in one piece, has been invented at Marriacourt, Mass. Round a block of wood shaped like a water pail, the machine cuts off a strip of the requisite thickness for a pail, and of the same length the block itself is. A piece of the strip, of the right length for a pail, is then cut off, the edges tongued and grooved, and a groove cut to receive the bottom.

Electro-Motors of the Future.

The difficulty in the way of the electro-motor at present is rather one of expense than of mechanics. The machine has doubtless been invented and tried on a small scale with a certain degree of success, but costs too much in working. Whether the electricity is developed directly from galvanic batteries or from a magneto-electric engine driven by steam, the expense in either case is greater than that incurred in obtaining an equivalent of power with the common steam engine. This has been proved over and over again, and constitutes the great stumbling block of inventors, though they may refuse to admit it. Must the attempts to produce a practicable electro-motor be abandoned, therefore? Not at all. The desideratum now is to find some means of greatly cheapening the production of the electric current. This should be sought, and probably will be found in some of the universally distributed forces of nature now untutilized by man or employed by him so sparingly. The doctrine of the correlation or interconvertibility of forces is now settled beyond dispute, and it only remains for the electricians to use it and call into being the most brilliant inventions of the future. The sunlight, as Ericsson has proved, is convertible into horse power by radiation and concentration. The wind has a capacity for work which man has but partially tested with his primitive mills. The tides, with their daily rise and fall, are sources of incalculable power now wasted all over the world. Every one of these tremendous natural forces awaits the coming man who will seize upon and utilize its strength, store it up as in reservoirs for use as required, turn it into electricity and conduct the resulting electric current by sufficient wires to points where work is to be done. Zinc and coal, or other substances by whose decomposition or combustion electricity is now produced are expensive. The sunlight, the wind and the tides cost nothing. They are free to all men, and only the competent inventor is wanting to make them do much of the work of the world, including that of steam locomotives—as a substitute for which the electro-motor cannot too quickly come to our relief.—*N. Y. Journal of Commerce*.

FIRE-RESISTING QUALITIES OF BUILDING STONE.—Dr. Cutting, State Geologist of Vermont, has concluded his unique series of tests on the fire-resisting qualities of building stones. He sums up the result in the current number of the *Weekly Underwriter*. He declares, in substance, that no known natural stone deserves the name fire-proof. Conglomerates and slates have "no capability" of standing heat; granite is injured beyond repair by even so mild a heat as that which melts lead; sand stones, including the variety called brownstone in this city, are better, and limestone and marbles are perhaps the best in this respect. But even they are injured by continuous heat of 900°, and at 1,200° are changed into quicklime. Therefore it would seem that no stone buildings are fire-proof, and some of them, Dr. Cutting even says, are as much damaged by fire as wooden structures are. Brick, on the contrary, is usually uninjured, and is often rather improved by heat until it is melted. But as most brick buildings are trimmed with iron or stone, the damage is often considerable, even when the walls stand. To avoid this, Dr. Cutting recommends soap-stone trimmings, which are open only to the objection of expense. But although brick stands heat so well, it is objectionable, because its power to resist pressure without crumbling from dampness or frost, is less than that of stone. Nevertheless, as brick is in fact only a kind of artificial stone, the search for an ideal building material is not hopeless, but it must be prosecuted rather by the maker than by the quarryer of stone.

AN IMPROVED ELECTRIC MOTOR.—M. Marcel Deprez, a well-known electrician, has brought out an improved electric motor, in which a piston of soft iron is attracted up and down in a hollow cylindrical electro-magnetic coil, with a motion like that of an ordinary steam-engine piston. This principle is not new, having been employed by Page, Bourbouze and Du Moncel in the construction of electro-motors. The novel point, however, about the motor of M. Deprez, is that the magnetism of the soft iron core is never either reversed or interrupted. This was the weak point of the earlier machines, but it has been obviated in the new form by the device of dividing the solenoidal coil into sections like the separate coils of the ring armature of the Gramme machine, the current being thus transmitted first to one part of the cylindrical coil and then to another. The commutator, which distributes the current successively to the various sections, is worked by an eccentric on the shaft of the fly-wheel in the ordinary way, but the "lead" does not require to be so much as a quarter of a revolution.—*The Iron Age*.

SCISSORS, the parts of which are still made in Sheffield, Eng., by a tedious hand process, are made at one stroke of a die in Connecticut. Hence, Sheffield sends to Connecticut for large quantities of steel blanks, which are forwarded in that form to Sheffield to be finished, and then returned to supply American customers, who will not be satisfied with anything but English-made scissors.

SCIENTIFIC PROGRESS.

American Astronomical Work.

The progress of science in the United States cannot be better illustrated than by a brief review of the astronomical work now in progress, and the instruments at the command of those making observations in this country.

Taking as our authority the "Report on Observatories," published by the Smithsonian Institution, and the "Annual Record" prepared by Prof. Edward S. Holden, of the U. S. Naval Observatory, Washington, we find that in 17 States Astronomical Observatories are located, varying in degree of importance from the National Observatory at Washington, to the possessor of a two-inch achromatic telescope of its owner's own make. The work done with the latter instrument being most instructive as showing how much really good scientific work can be done with limited means when directed by intelligence well applied.

The State of New York can boast of 12 observatories, Michigan four, Pennsylvania three, Massachusetts, Connecticut, Ohio, Missouri, Iowa, each two, and Tennessee, California, Mississippi, Minnesota, Indiana, Kansas, Illinois, Maryland have each one observatory. It will thus be seen what an immense territory is covered by American astronomers, ranging from the shores of the Atlantic to the Pacific coast, and from the tropical regions of the Gulf of Mexico to Lake Superior on the north. Many of these observatories are supplied with requisites appliances of the most perfect description, while all, with one exception, have at least a good achromatic astronomical telescope. * * * Among the largest equatorials directed nightly to survey the heavenly bodies may be mentioned the great 26-inch instrument, by Messrs. Alvan Clark & Sons, at the Naval Observatory, at Washington, under the charge of Prof. Asaph Hall (who has already made such important discoveries with it), assisted by Prof. Edward S. Holden; the Dearborn Observatory at Chicago possesses an 18½-inch equatorial (Alvan Clark), and the Harvard University employs a 15-inch equatorial by Mertz.

This powerful battery of astronomical telescopes of the highest excellence might seem to be sufficient for one nation, but the national spirit of American enterprise appears to be strongly infused into this great branch of scientific research, for new astronomical telescopes of mammoth proportion and exquisite perfection are now in course of construction for United States observatories, which, in the hands of the able astronomers ready to receive them, will doubtless add to their already well-earned fame and the prestige of science in this country.

With these facts before us, we read without surprise the note of Prof. O. Stone in our last issue, in which he says of a recently published "Record of the Progress of Astronomy during the year 1879," by Mr. Deyer, of Dublin, one-third of the memoir is devoted to the result of astronomical work done in the United States.

An article on this subject would be incomplete without a reference to the very perfect work of Messrs. Alvan Clark & Sons., of Cambridge, Mass., who appear to have distanced both the English and the Continental opticians in the excellence of their objectives, and who have secured to the United States the honor of supplying the objective for the great equatorial to be manufactured for the Russian government, to be used in the Pulkova Observatory by the distinguished astronomer, Otto Von Struve. We also notice that of the 40 observatories recognized by the Smithsonian Institute, 17 have telescopes made by this firm. In regard to the work now in progress at the Messrs. Clark's establishment, it may be stated without exaggeration that the world awaits with eager expectancy the result of their labors.—*Science*.

THIN ROLLED IRON FOR SCIENTIFIC PURPOSES. In experiments made at the Alleghany observatory, by Prof. Langley, on the measurement of radiant heat, he made use of a thermo-electric apparatus, a product of the American iron industry. Observations made with such instruments have shown that iron in extreme thinness is the most suitable material to be used with them, and in order to supply the demand, the Pittsburgh mills have succeeded in manufacturing rolled iron which is so thin that from 10,000 to 12,000 sheets laid on each other equal only one inch in thickness. An instrument made out of this material has almost the same responsiveness to radiant heat which the eye has toward light.

TO REMOVE THE OOR FROM BENZINE.—Mr. R. F. Fairthorne suggests, in the *American Journal of Pharmacy*, that if three ounces of powdered quicklime be added to a gallon of benzine, and the mixture be well shaken, most of the peculiar sulphureted odor of the benzine will be removed; and articles that have been washed in it will have no disagreeable smell.

HOW FLOWERS ARE RENDERED LUMINOUS.—We have already called attention to the preparation of luminous flowers which glow in the dark, and which are the latest elegant novelty offered for sale on the Paris boulevards. They are reported to have been rendered phosphorescent by coating first with a transparent size, and then dusting them with the phosphorescent salts of calcium or barium.

Danger in Toughened Glass.

Several accidents have recently been reported of the sudden explosion of drinking glasses made of toughened glass, one of which we give below as communicated to the editor of *London Nature*: A lady of my family emptied a powder composed of 7½ grains of carbonate of potash and 7½ grains of carbonate of soda into a tumbler of what is called toughened glass less than half full of cold water. After stirring the mixture she drank the contents, leaving a silver teaspoon in the glass, and then placed the empty tumbler on the table by her side, within, perhaps, a foot of a burning duplex lamp. About five minutes afterward a sharp explosion occurred, which startled all in the room. We found the tumbler shattered into fragments, the body of the glass ripped up, as it were, into several large, irregular-curved pieces, and the bottom of the tumbler broken into small pieces more resembling thick, rough ice than anything else. Query: Was the explosion caused by the inherent properties of the toughened glass, or by the contact of potash, soda, the silver spoon and proximity to a lamp, the heat from which was very slight; indeed, scarcely perceptible to the hand at the spot where the tumbler stood?

The accident might have been very serious, for pieces of the glass flew to within a very few inches of the lady's face. A solution of the cause of the explosion is therefore of considerable importance to all who may have occasion to use vessels of this peculiar glass.

We have not, as yet, seen any solution of the cause of such explosions, one of which occurred while the glass was yet in the hand of a person who had just quaffed its contents. We may remark, however, that toughened glass when broken does not present sharp edges, or points, as is the case with ordinary glass by which it is rendered more dangerous. Toughened glass breaks very much as does glass that is suddenly cooled, as Prince Rupert drops, which may be safely exploded in the hand and the broken fragments rubbed and handled almost as safely as so much coarse sand. The "explosions" probably arise from a sudden fracture of the outside skin of the glass, which from some reason in cooling, is drawn tight over the inner mass. In Prince Rupert drops that condition is caused by a sudden cooling of the outside by dropping the molten glass into water. Chilled cast-iron car wheels have been found in a condition under which a moderate blow from a hammer upon the face of the wheel has caused them to burst into numerous fragments.

A TABLE LAND ACROSS THE GULF STREAM. In a recent dredging expedition from Charleston, S. C., across the gulf stream, Commander Bartlett, of the United States Coast Survey steamer *Blake*, was surprised to find the depths much less than he expected. This induced him, although the trip was one primarily for dredging, to extend the work of sounding; and he accordingly ran a line of soundings nearly along the warmest band of the gulf stream, commonly called the axis of the stream, for a distance of 150 miles from latitude 32° to latitude 33° 30' north, on which he obtained depths varying from 233 to 450 fathoms, where it was supposed that the depths would range from 600 to 1,000 fathoms. At the northeast end of this line, in about latitude 33° 30' north, the depth suddenly increased, in a distance of 15 miles, from 457 to 1,386 fathoms. These depths obtained by Commander Bartlett appear to indicate that a submarine table land may extend from the coasts of North and South Carolina across to the Northern Bahamas. The development of this table land Superintendent Patterson proposes to have completed next spring, when the weather will be better adapted to such work than in the autumn and winter months.

THE MEXICAN CALENDAR STONE.—A Mexican archaeologist, Señor Alfredo Chavero, has written a book to prove that the famous Aztec "calendar stone" was never intended or used as a calendar. His study of Aztec hieroglyphs leads him to the conclusion that the stone was an altar of the Mexican sun god, and the characters, hitherto supposed to be signs of the zodiac, are records of Aztec cosmogony and theogony. When they are fully interpreted, he says, we shall know positively what progress the Aztecs had made in science and religion.

SUBMARINE TELEPHONE EXPERIMENTS.—A despatch from Paris, Saturday, August 14th, says that in the telephone experiments made on the submarine cable from Brest to Penzance, the Bell, Phelps, Gover, and Edison telephone systems were all applied and failed to work satisfactorily over the circuit. The new invention of Dr. Herz for telephonic communication over submarine wires proved a success.

TO REMOVE ARSENIC FROM SULPHURIC ACID. The purification of sulphuric acid from arsenic, which is frequently present in acid made from pyrites, may be effected, according to Telnic (?), by diluting the acid with half its bulk of water, and distilling after the addition of some plumbic chloride. All the arsenic, according to this author, goes over with the first portions of the distillate. In medico-legal investigations, this procedure may prove very useful.

NEW PHOTOGRAPHS OF THE MOON.—Mr. George Berwick, it is stated, has taken a series of photographs of the moon on very sensitive plate—the bromo-gelatin. One of the plates shows three well-defined rings around the moon. Whether the rings are due to comical, atmospheric, chemical or optical causes is not known.

which is said to be very rich with gold. This is probably the most extensive mining enterprise ever begun in this county.

EL DORADO.

MOUNTAIN VIEW.—Placerville Democrat, Sept. 4: Mr. Geo. W. Kimball informs us that the incline of this mine, near Gold Hill, is now down 90 ft., and the ledge is increasing in width and not decreasing in richness. The rock runs all the way from \$200 to \$1,000 per ton. A mill will soon be erected.

NOTES.—Prof. Tuck, a gentleman of extensive experience among mines in California and Nevada, came to Shingle Springs a couple of weeks ago, and immediately located a quartz ledge. He already has a portable steam mill on the ground, and will prospect his ledge thoroughly. If unsatisfactory, he will try some other point. This is a practical way of working, which commends itself to all sensible men.

MILL TREN.—The mill on the Reid mine has been leased and will be fitted up for the purpose of crushing a quantity of rock from the King-Island. Should the result prove satisfactory, it will be doubtless a substantial mill will be at once erected on the ground adjoining the mine which has been secured for that purpose. The mortar for the additional 5 stamps at the Chaparral was cast the other day at the Placerville foundry. The contract of the Grand Victory—successor to the Gross mine—is for a complete 50-stamp battery. This is in addition to the 30 stamps now at work. The 10 stamp mill for the latter is being pushed as rapidly as possible.

MAXWORTHY CREEK, FLUKE.—This mine is through the tunnel at the fundry, and rapidly extending toward Coloma street. Every precaution is being taken to hold it firmly to the bedrock. At the head of the tunnel a substantial stone bulkhead will be built, and a gate put in to guard against floods.

NAVYVILLE MINE.—Cor. Mountain Democrat, Aug. 29: The water is very low now, but there is still water enough in it to keep flat & Grindle's mill pounding away on good paying ore. Capt. J. M. Day, of San Francisco, has some men at work on his mine, the Little Mary, 2 miles east of here. It is an extension of the Central mine, and prospects equally as well as that.

KERN.

SLATE HANCO MINE.—California, Sept. 2: Old residents of Kern county may recollect the excitement which prevailed some 15 years ago about this district, lying in the midst of a vast desert region about 50 miles east of Walker's pass. Numerous ledges of unworked values were located, and many of them sold for what were considered great sums in those days. But the scarcity of wood and water, and the wide stretch of desert to be traversed in reaching them, were discouraging circumstances in the way of working them, and the excitement gradually died out. Later attention has been directed to the neglected district, and we learn that J. W. Searies, one of the discoverers, has sold a mine there for the sum of \$125,000. The 8th parallel railroad will pass through the district.

MARIPOSA.

YORKVILLE MINE.—Gazette, Sept. 4: We learn from Mr. J. W. Wilcox, who has just returned from a visit to the works of this company, near Florissant, that its 30-stamp mill will be one of the best he has ever seen. The distance from the mine to the mill is 4,000 ft., over which is constructed a railway laid with heavy T-rails, with improved automatic iron dump cars. The splendid mine of the company is in fine condition. The main incline shaft, which is 250 ft. deep, is newly timbered with redwood 12 inches in diameter, shipped from San Francisco. There is on hand already for crushing 3,000 tons of ore. The vein of gold at the bottom of the incline has taken a sharp pitch to about 50°. The main body of ore at the bottom of the shaft is 7 ft wide between clearly-defined walls.

NOTE.—During the past week, Mr. J. D. Coghlan, accompanied by a mining expert, has visited Little's Cove and the silver region a few miles southeast of this town, and has expressed his astonishment that such promising property should be permitted to lie dormant. Mr. Coghlan is a San Francisco capitalist, and he is highly impressed with the mining interests of Mariposa.

MONO.

BODIE DISTRICT.—Standard News, Sept. 1, gives these last official reports of the following mines:

SOUTH BOWEN.—Prospecting for the purpose of establishing the size of the ledge in the north drift by crosscutting at intervals of 50 ft., has developed a magnificent ledge 12 ft wide, carrying an ore vein of good milling ore about 6 ft wide. The Miller ledge never has shown a better indication of permanency and a well-defined ledge than at present. The quantity of milling ore in sight is estimated at 5,000 tons.

BOSTON CO.—The bottom of the winze is in vein matter with no change for the week. The upraise on the 200 level, from which the stope is started, is 22 ft high, and carrying a vein from 2 to 3 ft wide, showing ore extremely rich in gold. The stope is being extended, and at every point are looking well.

SOUTH NOONDAY.—There is little change to note, except that the clay seams in the crosscut running west on the 150 level, which has been advanced to a total length of 107 ft, appear to concentrate. Such indications are now shown ought to prove the existence of, and the near approach to a fine body of ore. This will probably be struck in the sand bank ledge.

WOMER.—The ledge has widened to 4 ft, nearly all ore and showing free gold. The walls are well defined, carrying heavy clay partings. The main tunnel, on a line with the Greyside ledge, averages 2½ ft of ore of a milling grade.

TIGRA.—The rock at the bottom of the shaft is very hard, and breaks quite short. There is a slight increase of water.

PACIFIC.—The station at the 600 level is completed, with a run of ladders connecting with the surface. The cable will next be removed from the north to the south compartment, safety cages inserted, machinery overhauled, preparatory to exploring the lower level.

LAKE DISTRICT.—We learn from William Welsh, Superintendent of the Glyn-Dale mine, that the prospects of the Mammoth company are excellent. The mine never looked better, and the mill is running steadily to its full capacity, and is crushing 84 tons of ore per day.

MONTICRISTO TUNNEL.—This tunnel has passed into a fine vein formation, and all indications in the face show its near approach to the Mammoth ledge, and this may be cut at any moment. The tunnel is now in about 1,000 ft. and will cut the ledge at a depth of 900 ft from the surface.

LISBON.—This is another outcrop extension of the Mammoth ledge. They have a good vein and are now working the ore extracted with an arastra, the rock being very rich in gold.

NOTES.—The adjoining mines are waiting for developments in the Mammoth, Headlight and Monte Cristo. There are now about 300 men at work in the mines and timber. A great deal of work is now being done on Laurel hill, with good prospects.

BISHOP CREEK.—Mammoth City Herald, Aug. 28: Charles Schumann, who has just returned from Bishop Creek, informs us that the Red & Boggs ledge, which is in the upper tunnel of their mine, which looks and prospects well. Numbers of specimens have been taken into Bishop Creek, and quite a little mining future is ragging there in consequence of the strike.

MILL NOTES.—A 10-stamp custom mill is about to be erected at Fish Springs. The company has purchased Antelope springs to supply the mill with water. Another 10 stamp mill is being erected at Keeler City, at the head of Owens lake, near the Cerro Gordo foothills mines, discovered about a year ago.

HOMER DISTRICT.—Index, Aug. 28: The May Lundy mine presents a busy scene just now. The working force is being rapidly augmented and operations are being extended with all possible dispatch. Last Sunday the main vein was struck in the tunnel, which is now 320 ft from the mouth. The strike was made a little more than 300 ft in. The vein is fully 4 ft wide, all clear ore of extraordinary richness. This striking the vein so large and so rich at a depth of 320 ft will settle the doubts of even the most

captious regarding the permanency of the mine. Ore is being extracted from the tunnel faster than the pack train can take it away, and the number of mules is to be increased next week from 10 to 30. The company is now negotiating to let a contract for packing down 1,200 tons of ore to the mill, the contract to be completed by the 15th of Sept.

NOTES.—Messrs. Land & Owens have let a contract to Mr. Jones for making a trail to the little Enant mine, and the work is now in progress. Ore is being taken out of the mine for shipment when the trail shall be completed. Jack Fallalain is busy getting his 1-stamp mill in running order. He expects to have it ready to commence crushing by the middle of next week, when it will start up on May Lundy ore.

NEVADA.

STRIKE IN THE BANXER.—Transcript, Aug. 28: For 3 weeks past 3 shifts of men have been at work putting things in shape in this mine, east of this city, to resume the systematic working of the claim. They have cleaned out the old Stiles & Tisdale incline, which is 100 ft deep, and run a drift 10 ft. In the face of the latter a 5-ft ledge of good-looking ore was encountered yesterday. As soon as the prospect of the ground is completed, if everything is satisfactory, the mine will be worked on an extensive scale.

NORTH END DISTRICT.—Kirkham & Hitchcock, at their Blue Tent claim, are now putting in a 4-inch Cornish pump, which will be run by a hand-wheel. Next week sinking for the 24 level will begin. One man has been engaged in stopping for 2 weeks past, taking out \$1,000 in silver.

SOUTH YUNA CO.—We are informed by the foreman of this company that the water supply will last this season till Nov. Lat, with 6,500 inches running in the main ditch steadily. It was not necessary this season to draw on the lakes till the 3d inst., whereas that is generally done early in July. The supply for all purposes will continue till a later date this year than ever known before.

GARRETT LODES.—Nevada City Herald, Aug. 28: Some good-looking rock is being taken from this ledge, situated near the Thomas mine. The quartz shows plenty of free gold and sulphurets. The ledge averages from about 6 inches to 1½ ft in width.

CORINTH MINE.—This mine, situated on Gillespie's ranch, continues to improve. About 1 ton of very good-looking rock is being crushed daily at this claim. The ore is of a fair size and contains both rich sulphurets and free gold.

FORTUNA MINE.—Work at this mine is progressing favorably. The principal labor now being done is drifting, sinking in the shaft having been stopped for several days. The company is taking out some good ore, and the ledge continues to improve both in size and quality the further they advance.

CLARK CREEK.—Oress Valley Union, Sept. 1: All of the rich specimens taken from the Rocky Bar mine last week, amounting to 750 lbs, have been run through the batteries of the mill, giving, in retorted gold, 667 ounces, worth \$17 per ounce, or a total of \$9,650. During the present week the ledge from which this rock was taken is being stripped, and it is not unlikely that more specimens will be brought to light when the miners come to "take up the law." A crushing of 10 loads of tribute rock has just been run through the mill, that gave a yield of \$40 per load.

ROSE HILL LEDGE.—This claim, on Winchester hill, gives promise of being a good mine. The first crushing, under last November's 5 loads, gave 2½ ounces of bullion, of the value of \$480.50. The next crushing was made in February, of 20 loads, which yielded 150 ounces of bullion, of the value of \$2,551.25. In June there was another crushing of 23 loads, yielding 182½ ounces of bullion, amounting to \$3,056. The deepest shaft is about 60 ft.

PURIFICATION LEDGE.—This crosses the Rose Hill ledge, and has 2 shafts, one 40 ft and the other 50 ft deep. From one of the shafts a crushing of 23 loads of rock was made in the early part of August, which gave a yield of \$694.75, or over \$30 per load. A crushing of 4 loads of tribute rock, and 4½ ounces of bullion, or over \$25 per load.

At the points where these shafts are sunk, the ledges are close together, and crosscuts connect the workings.

ALASKA.—George Mainhart has taken a 2 years' lease of the Alaska mine, of which he was a long time foreman. He is now getting the mine in shape to commence the extraction of quartz.

REPUBLIC.—A contract has been let for sinking the incline of the Republic mine 50 ft deeper. It is now down about 125 ft. A ledge 1 ft in width, of good-looking quartz, now shows in the shaft.

CONGREY.—No. 3 level of this mine is now being opened. The mine is now producing 60 tons of gravel per diem, and the 8 stamps of the mill are kept constantly at work.

PLACER.

DUNCAN HILL NOTES.—Auburn Herald, Sept. 4: Cwynn & Coode are driving in on their lead in Duncan hill, and are getting some very encouraging prospects. The rock shows free gold in many places, and all prospects rich. T. J. Hunter is getting his works in shape to follow the pay chute, when he expects to astonish the neighborhood with some more rich rock. Shurfield is still sinking on his ledge on the west side of the hill, and as he goes down continues to take out rich rock. This shaft, on the west extension, is now down about 110 ft. All the ledges on Duncan hill show well, and the manner in which some of them are now being developed indicate lively business in that section for the future.

PLUMAS.

SPANISH PEAK.—Quincy National, Sept. 4: During the past week very important strikes have been made in the Spanish Peak mine, which bids fair to open a section of the "old reliable" Blue Lead. The tunnel is underground some 1,000 ft, and is too high—that is, above bedrock some 12 or 15 ft. A shaft sunk from the head of the tunnel last week, developed about 3 ft of beautiful blue gravel on the bedrock, and the prospects obtained from it were wonderful, ranging from \$250 to \$5 to the pan. The rock is so rich that 20 can readily be seen in it.

OLD BLUE LEAD MINERS who have been on the ground say that it beats anything they ever saw in the blue-lead claims of Sierra county. The indications are strong that the gravel body is continuous and extensive, and there is every reason to think that several miles of the channel will be found intact under the lavas.

GREENVILLE NOTES.—The Acadian company has struck another large chimney of rich rock, and while prospecting for it they have taken out some \$3,000, which pays for all expenses and improvements.

CHEROKEE.—This company has erected large hoisting works near the old Kettle shaft. The building is 24x75 ft. The company has some 25 men employed on the Bellas mine. It is only a question of time when Cherokee will be in full working order.

COLD STRIKE.—This mine is now running 35 stamps on good paying rock.

MILL NOTES.—The Green Mountain mill, near the Crescent, will soon be completed. The mill, the large new boarding house and several miners' cabins near the new mill site, make a lively looking little city. The New York mill is running on the Red & Boggs ledge, and the ledge is in the upper tunnel of their mine, which looks and prospects well. Numbers of specimens have been taken into Bishop Creek, and quite a little mining future is ragging there in consequence of the strike.

SHASTA.—French Gulch.—Reading Independent, Sept. 2: The French Gulch district still continues to attract more or less attention. The Scorpion mine, under the management of McNevin, shows a large body of rich ore. There is talk of having the Washington mill crush a few tons of rock for test. An old tunnel, run into the mountain by the former proprietors of this mine, will be cleaned out and an attempt made to tap the ledge 100 ft below where they are now working.

LARGE YIELD.—We are informed by reliable parties that

a gentleman in Deadwood recently crushed 8 tons of rock, from which he cleaned up \$4,000, or an average of \$500 to the ton.

CENTREVILLE NOTES.—As there will be a sufficient amount of water here in a short time to supply the many miners of this vicinity, it will give them a chance to develop their mines, which have not been worked for the last 2 seasons for the want of water.

BUCKLEUP.—At this camp, Waupla & Lockhart have struck it rich. After sinking about 80 ft on their ledge with not very flattering prospects, they have at last come upon rock that pays 25 cents to the lb. The ledge is 2 ft wide, and as it goes down widens out like an inverted ledge. Big Charley, a miner in this locality, recently run 15 tons of rock through his arastra, cleaning up \$582.

SIERRA.

CALIFORNIA CO.—Downville Messenger, Sept. 4: This company, south of Table Rock, is employing 20 men, and find an abundance of pay gravel. Their tunnel is in 3,000 ft, 1 of which through very hard rock cost \$25 per ft to run. Work is vigorously prosecuted night and day.

FOREST CREEK.—The rock in this mine, near town, is found to be richer as they go in. The ledge is also widening out. This was a blind ledge, not showing on the surface at all.

BLICK GRAY CO.—This company, located 3 miles east of the 1001 mine, has struck blue gravel in their tunnel. They have only run a little over 100 ft, striking the lead on the end.

THE 1001 MINE.—The gravel in this mine is looking and prospecting better as they advance. The bedrock is becoming better and better, but very slightly. This claim bids fair to be not only one of the most extensive, but one of the richest in the county.

NEVADA.

WASHOE DISTRICT.

EXCHEQUER.—Cor. Virginia City Enterprise, Sept. 1: During the week have cut 350 ft water drain and relaid 300 ft of track. Have advanced north drift, 2510 level, 8 ft, making total length of same to date 42 ft. Face of drift all quartz. Started another drill hole north 10° east; are in about 60 ft. We have struck water, which comes out with such force as to prevent us from advancing.

SAVAGE.—During the past week we have completed the work of retimbering the main incline, having retimbered 18 ft. Have also retimbered 5 ft of the main shaft. Continued east crosscut, 1300 level, 6 ft, and then stopped drifting it. Commenced driving northwesterly upon the same level, and have driven 27 ft, through mixed ground of quartz and porphyry. Have been engaged in putting in a new tank at the 2000 level, which is not yet completed.

CALDONIA.—The pump has been run an average of 17½ hours per day. Have pumped Belcher water a part of the week. Forman shaft has been sunk and timbered 20 ft; total depth, 1,380 ft. Rock continues very short and tough. Water has increased considerably.

CON. IMPERIAL.—No. 3 crosscut west, 2810 level, 350 ft north of the main winze, is in 35 ft; face is hard porphyry. Very little work has been done in the Imperial during the past week, as we are employing most of the miners in the Exchequer mine.

OVERMAN.—The winze from 1900 level has been sunk 20 ft; total depth, 86 ft. Forman shaft has been sunk and timbered 20 ft; total depth, 1,380 ft. Rock continues very short and tough, and water has increased considerably.

CHOLLAR.—The diamond drill has been run 150 ft in a southwesterly direction from a point in the Chollar south drift 500 ft south of the main west drift, and through porphyry, clay and quartz.

GOLD & CURRY AND BEST & BECHLER SUAPT.—Have sunk and timbered the shaft during the past week 25 ft; total depth, 1,555 ft.

BECHLER.—Preparing to put in the new pump-rood.

CAYOUSTE.—Hill City News, Sept. 8: The joint Ophir crosscut east, on the 2000 level, is making usual good progress; no change in material to note. The joint Ophir raise from 2300 level is advancing as usual. The north drift on this level, to connect with the workings south from the Ophir line, is averaging 3 ft per day. The stope on the 1050 level continues their yield of fair-grade ore.

ORIN.—The south drift on the 2500 level, toward the C. & A. shaft, is averaging 4 ft per day, and is without particular change. The drift on this level north and east is making usual progress, and is following the streak of heavy vein matter which was cut in running east from the incline.

BRISTOL DISTRICT.

BRISTOL CO.—Pioche Record, Aug. 28: The company's mill dropped stamps on the 25th. The roaster and everything connected with the mill is running smoothly. A large assay office and retort-room will soon be completed, and when finished they will be the finest ever erected in the county. About 25 tons of ore are being handled daily from their mines, and this amount can be doubled any time.

HILLSIDE CO.—The furnace of this company was started up last Tuesday, and is running nicely, turning out the usual quantity of bullion. There is quite a large amount of coal and ore on the dump, and there is every prospect for a long and continued run. A new cupel furnace is about to be put up, so that they will have facilities for refining all the bullion. Work will commence upon it tomorrow. Both of the mines are looking well and turning out their usual amount of good ore.

IRON MINE.—Chris. Kastberg has sold this mine, located in this district, and the ore is now being reduced at the furnace. It is looking well and turning out 5 tons of good ore per day. It is very fine smelter ore, carrying from 40% to 60% lead. The ore is mostly carbonate, with some siliceous. A good road is already completed from the mine to the furnace.

DUN GLEN DISTRICT.

DUN GLEN.—Silver State, Sept. 4: The Lang Syne mill, at Dun Glen, is running steadily day and night, and the ore is said to be paying handsomely. The ledge, which almost run down to a seam for several ft, has opened out again, and is now 3 ft wide in the drift, and carries very rich ore.

EUREKA DISTRICT.

WALLES CO.—Sentinel, Sept. 1: We are informed by Supt. Griffith that the rumors of a development in the Wales Co. are true. About 10 ft of ore, mostly low grade, has been encountered in the east crosscut from the 300 level. There are some rich streaks and spots in it, but the mass as a whole is not high grade. Assays have been obtained ranging from \$43 to \$226. The extent of the find has not yet been determined, though it is regarded as very important. The mine is being worked day and night.

ZULU MINE.—An important strike has just been made in this mine, situated south of Ruby Hill. On the 45 level a vein of ore 2 ft thick has been encountered, which is extraordinarily rich. The specimen are said to be the finest met with in this section in a long while. The main shaft was reached at this level, and a crosscut was started, and has been started for the ledge. There is no doubt that the vein found above will be cut by this crosscut as soon as it shall have been advanced a little further. All in all the Zulu is a promising property.

GALENA DISTRICT.

MINING NOTES.—Winnemucca Silver State, Aug. 31: Frank Drake, formerly Commissioner in this county, arrived in town last night, from Galena, where he has been engaged in mining for 11 years past. He says the Galena mines are attracting considerable attention, and Eastern companies are investing there. He has sold an interest in the Silver Point mine, adjoining the North Trinity, for \$5,000, and he expects to realize 10 times as much from another location which he owns on the same lead.

CENTRAL ORE.—A lot of ore from Central was taken to

the Humboldt reduction works yesterday. We learn that there is plenty of ore at the Teamster and other mines in Central that will pay the owners to have worked here.

MINERAL HILL DISTRICT.

MINING NOTES.—Cor. Eureka Sentinel, Aug. 29: Matters at this place are progressing quietly but steadily. The company is working its mines with good results, and has somewhat increased its working force. They sort the ore, and will make the first run on rich rock. When the stamps are dropped it will be on a quality of ore which will make the returns both mild and heavy. Mr. George Buchanan is still working his property single-handed, and is doing better, probably, than any wages-laborer in the State. The vein is small, but he puts in every day, Sundays excepted, and, it is claimed, cleans up an average of \$4 per day the year round.

PHILADELPHIA DISTRICT.

MINING NOTES.—Belmont Courier, Aug. 28: The mines of this district—the Belmont, Highbridge, Monitor-Belmont, El Dorado South and a number of others—have yielded large quantities of rich ore above water level, all but the Belmont are shut down at present. The Belmont is never out of ore. There is a well-defined, mineral-bearing ledge in the 600 level, but the ore is of a low grade. The other mines have well-defined ledges, carrying ore, dipping the same way as the ledges do in the Belmont. The Belmont has 3 or 5 of these companies, by putting up heavy machinery and sinking a shaft to a depth of 1,500 or 2,000 ft, could thoroughly develop their mines, with as fair a prospect of striking a bonanza as any mine in the county.

PIOCHE DISTRICT.

DAY MINE.—Record, Aug. 28: The last official report says that the body of the 300 level is still holding its own; which looks well for another continuation of ore. Crosscut in east winze shows well, and as they advance more ore is coming in the face. The 400 level crosscut shows bunches of ore and looks more kindly. The 400 level looks about the same as last report, finding bunches of ore out across an open fissure, which looks well; face in ore and spar, and very strong. Main shaft advancing fast, considering the nature of the ground.

SPANISH BELT DISTRICT.

BARCELONA MINE.—Belmont Courier, Aug. 28: We visited this property lately, and found them engaged in improving the ventilation of the works. There is a solid ledge in the north crosscut, 4 ft of which is mineral of a high grade, rich in sulphurets and carrying a good percentage in gold. This ledge widens as it goes down and the ore improves in quality. A winze will be sunk from the 300 level as the connection is made, and the tunnel section continued to the Barcelons Core incline, at the bottom of which is a 12-ft ledge rich in sulphurets. The prospects in this mine warrant the erection of a mill, and the sooner it is built the better it will be for all concerned.

ARIZONA.

GLOBE DISTRICT.—Silver Belt, Aug. 23: Mr. Morehouse, the master carpenter at the Nugget mine, informs us that it is looking better than ever. He showed us some very fine ore taken from the bottom of the shaft, 120 ft down. The ledge is nearly 3 ft wide, and every particle of it is in good milling ore.

GERMAN FRIEND.—Mr. Hayse has laid upon our table some specimens from this mine. They are coated with horn silver. Upon this ground and in its immediate vicinity, large quantities of almost pure silver float have been found. Mr. Hayse's books show that \$3,000 have been taken out of the mine at a cost of \$150, independent of 500 ft of rich float.

NOTE.—They have struck high grade ore in the Anything mine, near Ramboz camp. This is an extension of the Diana.

PINAL DISTRICT.—Cor. Silver Belt, Aug. 25: The Silver King is still looming up. They have considerably increased the number of underground miners, and continue to send up quantities of rich ore from their bonanza. Their new machinery, and the improvements on the improvements on the dump facilitates labor.

NOTE.—A good deal of mining and assessment work is being done in this district, but there are many men waiting and seeking for employment.

EUREKA DISTRICT.—Yuma Sentinel, Aug. 28: We learn that the mines in Eureka district are attracting capital, and there is a strong probability of great activity in that section this fall. These mines are known to be rich as far as developed, and in availability they cannot be surpassed, wood, water, labor and transportation being within easy reach and cheap. A judicious expenditure of money upon these mines will undoubtedly develop immense wealth, and insure a splendid net yield to investors.

TURKEY CREEK DISTRICT.—Prescott Miner, Aug. 27: We were to-day, shown some pulp from the first run of the new mill on Turkey Creek, belonging to the new mill of the Arizona Co. mill and mining company. In fineness it is fully equal to the product of any stamp mill that we have ever seen, yet we are informed that the machinery is capable of reducing to a much finer powder if necessary. The machinery used in this mill is new, not only to Arizona, but to the entire Pacific coast; it has, however, been largely used in Eastern quartz mills with the most satisfactory results.

ANTELOPE PEAK.—Phoenix Herald, Aug. 25: A Mexican named Losaro found recently on the west side of Antelope Peak, 15 miles north of Wickenburg, a gold nugget weighing 12½ ounces, and valued at \$220. Antelope Peak is a well known placer ground, and thousands of dollars have been taken from it.

BIG BUG DISTRICT.—Prescott Miner, Aug. 27: A correspondent of the Chicago Economist, writing from Big Bug (near Prescott), July 14th, gives a glowing account of the richness, number and size of the mines on Big Bug, together with the mills in progress and prospect. The writer predicts that when the A. & P. R. E. is completed, Big Bug will become another Eureka. The writer is in business activity, and is much more daring in reason of the vertical and fissure character of the ore deposits.

IDAHO.

LEMIN COUNTY.—Yankee Fork Herald, Aug. 28: The Bachelor lode lies nearly 3 miles easterly from Custer hill and on a parallel ridge. One of the owners brought down some of the ore this week. It is the same character of quartz as that of the Custer and adjacent mines, and the specimens shown us were full of silver sulphurets, worth from \$800 to \$1,000 per ton. The prospect shaft is down 30 ft, and at different points in it come very high grade ore is encountered.

WOOD RIVER.—Bellevue cor. Idaho City Statesman, Aug. 15: The mines about this place are looking very well. Good reports come in from all the camps in this vicinity. Ketchum and vicinity is looking well. Col. Shepherd at Galena has struck a large body of fine ore in 2 of his ledges at Galena, 1 of which assays \$17,000 to the ton. Many of the miners are shipping ore to Salt Lake. Among those are Messrs. Pease & Taylor, of Galena; Johnson & Co., of Minn. Tooth; Root, of Ketchum, besides several from Boy's gulch near this place.

NOTE.—I have visited a great number of mines in all the camps in this country, and as I go from one to another am only confirmed in the opinion expressed in my former letters, that this country will, in a very few years, astonish the world with its richness.

DOUGLASS COUNTY.—Idaho City World, Aug. 27: Jas. Irwin and Ben Miller discovered a lode the other day on Crooked river, 6 miles from Banner, and a mile and a half from the discovery made a short time ago by Messrs. Miller & Lester. The ore assays \$126 per ton in silver. The rock carries gold also, but to what extent is not known, as no assay has yet been made except for silver.

DOUGLASS COUNTY.—Silver City Avalanche, Aug. 27: There are some ledges in the vicinity of the Leonard mill, which have been looming up finely during the past few weeks. Among the prominent lodes there are the Whey Gulch, Rob Roy, Addie Leonard and others.

Subterranean Kaolinization—The Comstock Lode.

We find the following letter from Mr. John A. Church in *London Nature*, for August 5th. It will be read with interest by all who are interested in the scientific study of the Comstock lode:

A year ago Mr. John Arthur Phillips, in criticising, before the Geological Society, my theory of kaolinization as a source of superficial rock temperatures, made a point which is interesting in its bearing upon the composition of derived or secondary lithological products. He endeavored to ascertain this number of tons of felspathic rock that must be yearly kaolinized in order to supply the quantities of alkalies known to be contained in the mine waters of the Comstock silver lode in Nevada, and in doing so he began with the supposition that in the process of kaolinization all of the alkali in the feldspar goes into solution and is removed. This assumption is undoubtedly incorrect, for even the surface clays which are deposited from running water, and therefore must have been subjected to a maximum leaching, almost invariably contain potassic and sodic salts, as any one may learn by studying this subject of fire-clays.

But when the clay is formed by the alteration of rock at great depths, beyond the line of ready drainage and in the presence of a minimum quantity of water, the product is, or may be, quite different from the clay of sedimentary deposition. It is in fact merely the original rock hydrated, and from the example given in the Comstock region the alteration product does not seem to lose much, if any, of its original alkalies. This is demonstrated by the analyses given in Mr. King's report on the fortieth parallel. All the existing analyses of the clays in this region were made on specimens obtained in the first 1,000 ft. of depth, and most of them were taken within 500 ft. of the surface. That is, they all come from the region of active drainage, the oxidizing and other effects of atmospheric action being well marked in this lode down to the depth of 600 ft. The mean of four analyses of clays show 4.72 of alkalies and 10.86 of water, CO_2 2.05. One of the specimens has been very grossly altered, having lost about 10% of silica, while another seems to have gained about half as much of the same constituent. As to the composition of the original rocks (propylite and andesite) it is impossible to be exact, for the alteration in the region has been so extensive and thorough that all attempts to obtain an unaltered specimen have failed. The least altered specimen of propylite from the Virginia range of mountains in which this lode is found contains 5.08% of alkalies, with 1.02 loss by ignition. The most altered specimen contained 5.26% of alkalies, and 6.53 loss by ignition. Andesites showed in the least altered specimen 4.7 alkalies and 2.8 loss; in the most altered specimens 7.37 alkalies and 4.35 loss. It is impossible to compare the clays of this district with unaltered rock from other localities, for the reason that the composition of these eruptive rocks varies strongly, especially in the percentage of alkalies. On the whole I think that any one who will compare the tables of analyses given in Vols. I. and III. of Mr. King's work will be convinced of the truth of what I have asserted above—that subterranean kaolinization is merely the hydration of a rock in place without other serious alteration. The fact has importance in its relation to the origin of some hydrated aluminous rocks.

Mr. Phillips calculates that the average proportion of alkalies in these rocks is 6.4%; that 813 tons of alkalies are removed yearly in the mine waters, and that "it consequently follows" that the feldspar in 12,703 tons of rocks "must be annually kaolinized, and the whole of the alkalies removed in solution." It seems to me that a metallurgist of Mr. Phillips' experience should have known that the alkalies are never completely removed in kaolinization. That he is not acquainted with the peculiar and remarkable conditions of the Comstock is not surprising, for the lode receives but little attention, and that of the most hasty kind, from visitors. I ask your permission to add the following summary of facts which rebut Mr. Phillips' criticism:

1. The removal of alkalies in subterranean kaolinization, if it is judged by the existing incomplete series of analyses, seems to vary from less than one-fifth of the quantity of alkalies in the present rock down to almost nothing.

2. The whole results of kaolinization are not represented in the mine waters. In the vast areas of dry rock alteration has been extensive, and seems to be going on by means of water-vapor, and none of this action supplies alkalies to the mine waters.

3. The liberation of hot gas which is an accompaniment of kaolinization by atmospheric waters conveys the heat produced in the dry areas to all parts of the mass, and especially to such channels as watercourses and mine-openings.

4. Kaolinization in the Comstock region is not produced by the action of cold water on cold rock, but by the combination of water and rock, both already heated before the action to very nearly the temperature they attain after it. The heat of the rock is cumulative, its present temperature being mainly the result of ages of previous kaolinization, the heating effects of which were preserved from dissipation by a

blanket of rock 1,000 ft. thick. The water which takes part in the action at existing depths of the mine has been heated by its percolation through 1,000 to 1,500 ft. of hot rock lying below the blanket spoken of. Mr. Phillips calculates that 85° are added to the temperature, but in fact the actual increment of temperature by kaolinization is, in the locality given, but a small fraction of this quantity. Considering the small rainfall of Nevada, and the depths at which the waters are now drawn from the rocks, and the perfect correspondence of depth and temperature, it is more probable that the actual gain of heat does not exceed one or two degrees, and may even be less.

5. Mr. Phillips' calculation that 330 tons of water are heated by the kaolinization of one ton of rock has no foundation in the known facts, but it is probably more than 99% from this truth. His further error in supposing that the increment of heat is 85° F., instead of being in the neighborhood of 1°, as is more probable, relieves his criticism of whatever weight it might have if it had been adjusted to the well-known facts of the case.

The Gatling Gun.

This deadly and most useful weapon in certain circumstances of modern warfare has of late undergone several modifications in detail at the hands of the inventor, Dr. Gatling, who has recently had it on view at the offices of Sir William Armstrong & Co., in Great George street, Westminster. In the old-pattern gun, the cartridges were supplied from a large drum which was placed end upwards over the gun, the cartridges being delivered somewhat to the side of the weapon, and, therefore, out of line with its axis. The firing-handle was placed at the other side, and the barrels and working parts were more or less exposed. All this has now been altered, and the modified gun presents several new features. In the ten-barreled weapon, which we recently had the opportunity of examining, the barrels and the working parts are enclosed in a gun-metal casing 27 inches in length and 6½ inches mean outside diameter. Each barrel is 18 inches in length, the outside appearance of the gun being that of a howitzer. The crank-handle is now placed at the rear, instead of at the side, and by a re-arrangement of the firing mechanism the speed of the revolution of the gun and the rapidity of its fire has been greatly increased, so that it is claimed for it that it fires 1,000 rounds per minute, the ordinary rate of rapid firing being 750 rounds per minute. That it is well able to fire the larger number appears probable from this rapidity with which it was manipulated with dummy cartridges on the occasion of our inspection. The feeding is now effected from magazines or long cases, each capable of containing 40 cartridges. The case is placed vertically over the center of the lock-chamber of the gun, and the cartridges fall directly into the receivers. As soon as one case is emptied another takes its place, there being two attendants required, one for this work and the other to turn the handle. The barrels and locks revolve together, but in addition to this action the locks have a forward and backward motion. This is effected by means of a cam-path, up which each lock travels and pushes this cartridge home. It then fires it, and returns down this path, ejecting the cartridge-case from the side of the gun as it returns. This gun can be fired only when the barrels are in motion from left to right; and so long as the crank-handle is revolved and the gun fed with cartridges the several operations of loading, firing and extracting are carried on automatically, uniformly and continuously. Should the crank-handle be turned in a reverse direction no harm results to the gun, as the interior form of the receivers admits of reversing the motion without danger of jamming the cases. The traversing arrangement has also been simplified, and lateral play can be given to the storm of bullets that can be delivered uniformly with the firing of the piece. It will thus be seen that the gun has been greatly modified and improved, and reports from America show it to be capable of some very remarkable performances, both as regards rapidity and accuracy of fire. Dr. Gatling has made one of these guns for our own government, which will fire the Boxer cartridge, although he prefers the more solidly-made cartridges of the American pattern.—*Hardware.*

SOUND ADVICE TO YOUNG WIVES.—Some sound advice is given by a sensible matter-of-fact person to young wives, who are recommended not to worry as to how they can recover the lover, who has become merged in the husband. Ten to one he cannot be recovered. He is probably as dead as King Thotmes of the obelisk, and quite as probably never lived, save in the imagination of the woman he has married. The man beside the fire—not, of course, at this season—who drops asleep while his young wife is telling a funny incident about the last five o'clock tea, is very likely an excellent, respectable person, with no nonsense about him, who is worth ten such lovers as he was imagined to be.

THE ECONOMY claimed for the Perkin's high-pressure system, as developed in the little English steamer *Anthracite*, is to be verified by a careful experimental trial of her engines in New York. The owners of the steamer, having sufficient confidence in their claim, have placed her for that purpose in charge of competent United States naval officers.

A French Co-operative Scheme.

M. Godin, of Guise, France, turned over to a co-operative corporation one of the most extensive iron foundries in France, which he had built up, as all great businesses are built up, by enterprise, economy, honesty and intelligence. The company took his business at an appraised value of 4,600,000 francs, the payments to be 5% interest until Godin is bought out. It is managed by a board of directors, with Godin at the head, and in the division of the profits the workmen are entitled to a dividend on their wages, at the same rate as the dividend on the stock. For instance, the net profit last year, after paying interest and all other expenses, was some \$40,000. This profit was made on an outlay of \$300,000 in wages to labor, and \$40,000 interest to capital; accordingly, the stock receives less than one-seventh of the net profit, and the other six-sevenths is distributed among the workmen as the dividend of labor. All the workmen share in this dividend, and, as the result of years of teaching and preaching, many of them have invested their surplus wages in the stock, so that they are both capitalists and workmen.

In addition to this ownership of the establishment by the workmen, there are model lodging-houses, restaurants, baths and schools where the workmen can get all the comforts of life cheaper than the discomforts of life cost them outside. In spite of the attractions and advantages offered by this "social palace," as it is called, a majority of the workmen prefer the freedom of their own more expensive and ill-kept homes. Mr. Godin is reported as saying that his regrets having made his experiment with such dull and unpromising material as the workmen of Guise, who are, it must be admitted, deficient in point of intelligence; but in spite of these drawbacks something has been accomplished. Such a thing as a strike has never been known at Guise, the business has been uniformly prosperous, the workmen are better paid, better housed and in better condition every way than they would have been if Mr. Godin had been a mere capitalist intent on selfish enrichment; but the vital question is, is the arrangement permanent? The depressing answer is "No."

A single incident shows that the success of the experiment so far has been the result of a single will controlling the whole scheme, and that even among workmen trained by years of experience in the benefits of co-operation the selfish instinct of immediate individual gain overpowers their desire for a remoter gain through the general well being. Some time ago a rule was drawn up enacting that an allowance out of the general fund should be made to all workmen who fell ill and could not work. This allowance was to be paid from the day the illness began. Shortly after this had been decided upon the committee found the number of illnesses increased in a most suspicious manner, and the relief fund diminished rapidly. A new rule was made providing that no allowance for sickness was payable till the patient had been ill three days. This new arrangement had a miraculous effect upon the health of the *Familliere*, and the fund was soon as large as ever. Seeing this, the committee reverted to the original rule—of course with the same result as before. The relief fund dwindled away in a twinkling; and for the sake of the workmen's health—not to speak of their morality—it was judged advisable to abandon the instantaneous relief plan.

One such incident sets aside the whole experience of years in the attempt to establish human relations on any other basis than that of selfishness. When we speak of an enlightened selfishness as the basis of society, we may rest assured that the measure of enlightenment in the selfishness will be the measure of enlightenment in society, and there is no existing society in which the wage-earning class is sufficiently enlightened to carry on with success such a project as the kindly, generous heart of Godin has devised. There is no use in sentimental regrets over the failure of experiments carried on under conditions which render success impossible, and the failure of the Guise *Familliere* will merely prove that Godin was too early with his reform. If we were to seek a law or formula by which to describe the inevitable failure of such experiments, we might say that in a condition of society in which they are practicable they will not be needed; or, we might say that workmen intelligent enough to profit by them will be, and are, intelligent enough to get along quite as well without them.

DEFECTIVE PATENT LAWS.—The British patent laws certainly demand both revision and amendment when so cautious a man as Mr. Crooks, who has made not only notable advances in science and the arts himself, but has been the ready and honest exponent of what has been accomplished in both by others, is compelled thus to express himself: "We know of a certainty that there are men in England who refuse to tell their ideas to the public, because they will obtain nothing in return, except some reply such as that they are not the true inventors, and proof is expensive."

EDINBURGH'S educational department are of the opinion that it is of the utmost importance that reading should not be taught out of one set of books. Two or three sets ought to be used in every school in order to prevent the habit of learning by rote through constant repetition, and to accustom the children to read any book at sight.

Measuring the Velocity of Light.

Prof. Simon Newcomb has finished an apparatus of great scientific interest and value for measuring the velocity of light. Though the principles of its construction are not new, the details are such as to insure increased accuracy. Its most conspicuous parts are two brass tubes, eight ft. in length by about two inches in diameter, placed horizontally at right angles to each other, like the two branches of the letter L, and resting at the angle and at the outer ends upon low, solid columns of brick and stone. These tubes are telescopes, differing from ordinary instruments only in respect of their great length and small diameter. One of them is immovably fixed upon its bed of masonry, while the other—being laid in a plane about two inches lower with its "object" end upon a pivot—swings by means of a delicate screw to the right or left through a radius of 1° or 2°.

At the angle formed by the line of the two telescopes, and placed so as to be in the line of vision of both, stands a small mirror of peculiar construction. It is a square column of steel, five inches in length by two in diameter, and pleted upon its four sides with nickel. It is mounted, top and bottom, upon pivots, so as to revolve horizontally, its motion being given to it by a rawhide cog-wheel. Affixed to one of the wheels which give motion to the mirror is a device for breaking an electric current, connected with a recording clock, so that the number of revolutions of the mirror each second is automatically recorded. The power to give the mirror its revolutions is furnished by a steam engine built for the purpose, and placed in an adjoining building.

A few ft. distant from the eye glass of the fixed telescope, and in a direct line with the instrument, is placed a helioscope—an apparatus consisting of a mirror mounted upon complicated bearings and moved by clock work, so that when wound up and adjusted it will follow the apparent motion of the sun, reflecting its rays for any desired length of time upon a given point. The rays of sunlight thrown from this instrument are brought to a focus by an intermediate lens upon the eye glass of the fixed telescope, through which they pass to the surface of the revolving mirror at the other end.

At the Naval Observatory at Washington, some 8,000 ft. distant from Fort Whipple, across the Potomac (its exact distance will be ascertained by the coast survey before actual work is begun), is placed a fixed mirror, circular in form, three ft. in diameter, and of such a delicate degree of concavity that light thrown upon it from the revolving mirror at the fort is returned again and brought to a focus as near as may be upon its starting point. In other words, this mirror is a section of the inner surface of a shell which, if complete, would be three miles or more in diameter. Of course, to all appearance, it is perfectly flat.

Now, to understand the working of the apparatus, let it first be supposed that the revolving mirror is at rest. The course of the sun's rays will be as follows: Striking the mirror of the helioscope, they will be reflected through the intermediate lens upon the eye glass of the fixed telescope, through the instrument to one side of the revolving mirror, thence to the concave mirror across the Potomac, by which they are returned to the revolving mirror, and are finally reflected through the movable telescope to the eye of the observer placed at the eye glass. This point at which the telescopes rest to receive the sun's rays after they have made their tortuous journey, the revolving mirror being at rest, is marked zero. Now apply the same and set the revolving mirror in motion. Give it 200 revolutions a second, and its four sides will throw 800 reflections of the sun's rays across the Potomac to the mirror at the observatory. The observer no longer catches the sun's reflected rays through the movable telescope at zero, but swings his instrument to the right or left, according to the direction in which the mirror is made to revolve, until they again reach his eye. Reflections, following each other with such enormous rapidity, appear as a single reflection.

This, then, is the whole process. It remains only to note the number of revolutions per second, as indicated by the recording clock, and the degree of deflection from its normal position at zero given to the movable telescope, and work out the result as a "sum" in arithmetic. It will be seen that, while a ray of sunlight is making its journey across the Potomac and back, between the revolving mirror and the fixed concave mirror, the former will have made some portion of one of its revolutions. This portion is represented by the degree of deflection which it is necessary to give to the movable telescope to catch the rays upon their return and second reflection from the revolving mirror.

The following propositions, penciled by Prof. Newcomb, illustrate more accurately the results to be attained from given hypotheses: Speed of mirror, 200 turns per second; deviation of reflecting ray, 2½°; distance, 1.6 miles. Results: Motion of mirror in one second, 360° × 200 = 72,000°; observed motion of mirror while light is going and coming, 1½° is 72,000 ÷ 1½ = 57,600. Then velocity of light = 2 × 1.6 × 57,600 = 184,320 miles per second.—*Iron Age.*

THE Portneuf Falls, southern Idaho, are described as grand in the extreme. For several miles there is a succession of cascades, falls and deep pools full of trout.

THE ENGINEER.

The Belgian Cable System on the Erie Canal.

Great expectations are entertained in regard to the success of the introduction of the Belgian cable system upon the Erie canal. A company has been formed to carry out the project, which will at first operate over a given section. A wire rope is now being laid for a distance of 250 miles, and 18 cable tow-boats have been built with which to operate. Towing has already commenced on the first section of 60 miles, between Syracuse and Utica, and boats will soon be taken by cable over the whole length of the wire.

The *modus operandi* is as follows: The wire rope is laid on the bottom of the canal and fastened at the two ends. Now, suppose a man in a small boat wishes to come to Utica, and draw four, six or eight small boats behind him. He simply sits in his boat and pulls on the cable in an opposite direction from Utica; the operation would naturally force the boat east, and its continuance would eventually bring the first boat and the boats connected with it into Utica. The occupants of the boats attached in the rear, not taking hold of the cable, must do their share of work by steering so as to keep the line from swinging, like a whip-lash, from one side of the canal to the other.

When a tow or tug-boat is employed, the tug takes the place of the small boat, its "clip wheel," which grasps the cable and pulls, represents his fingers, hands and arms, the powerful engine and boiler supply the muscle, and the string of six or eight canal boats connected in line by hawsers represent the small boats behind the first skiff.

The company charges 20 cents a mile per boat for towage, which is the same as has heretofore been charged for horse towage; but while cable towing costs the same as animal power, it increases the profits by doubling speed. The cost is uniform during the season. The system is to be applied to all the canal boats, say 3,000, now in commission on the Erie canal. Animal power cannot compete with the cable system. Any increase of charges by the company would cause a return to the use of animals. Except it is greatly to the profit of the boatman, he will not patronize the company. The company cannot become a monopoly, as its chartered rights do not interfere with the free use of the canal.

The cable is seven-eighths of an inch in diameter, made of Bessemer steel wire, in six strands of seven wires each. Thirty miles cost \$18,000 and that quantity weighed 80 tons.

New Developments in the Mississippi River Improvements.

Several new features of an important and interesting character, and quite independent of the deepening of the channel, have quite recently been developed, as growing out of the improvements in progress at the mouth of the Mississippi. That which most deeply interests the general public is the light that is being thrown upon the problem of controlling the tremendous forces of the Mississippi river, so as to secure constant and practical navigation from St. Louis to the mouth, to maintain an approximate uniformity of channel and velocity of current, to regulate the caving of the banks, and to modify the annual disasters from floods. These are questions in which the people of the vast Mississippi valley are directly and individually interested, and in which the prosperity of the entire nation is largely involved. The successful solution of this problem will contribute to the enrichment of 14 great and growing States. It will reclaim to civilization millions of acres of lands of unexampled fertility, populate a vast empire now practically uninhabitable, and more than double the productive capacity of the valley.

The most interesting and important fact revealed by the present inquiry is the singular effect upon the river bed produced by the spring floods. Investigation shows, beyond all doubt, that, during these floods, the river bed is raised throughout the whole extent of the stream, and, in many cases, to a point considerably above the low-water mark of the summer. As soon as the river channel fills, and the water begins to spread out over the lowlands, the velocity of the current is checked, and the enormous masses of earthy matter previously held in suspension are deposited. This process continues so long as the river remains up, and it goes on with such rapidity that the bed is gradually raised and the water thus lifted out and over the banks. By these means the volume and duration of the annual overflows are incalculably augmented, and thus it appears that the execution of the plans to prevent the spreading of the river and formation of bars will exert a direct and powerful influence for good upon the destiny of our alluvial lands. It seems, then, that the jetty principle, which has given New Orleans the finest deep-water harbor and outlet in the world, will also give to the Mississippi river a permanent and reliable navigation throughout its length, and to the alluvial region of the valley a great and sorely-needed relief from the calamities which now impoverish and depopulate that fertile territory.—*New Orleans paper.*

USEFUL INFORMATION.

The Flavor of Meat.

M. Moular, a noted agriculturist in France, has suggested a singular plan for varying the flavor of meat. He imagines that by feeding cattle, sheep, pigs and poultry in a particular way, or rather by flavoring their food in various ways, their flesh may be rendered much more agreeable to the palate than it often is; and there can be no doubt that he is substantially right. Thus, for instance, it is well known that poultry which have been fattened upon food containing a slight admixture of chopped truffles are far better eating than those chickens which have been stuffed or larded with truffles after they are killed. It is only natural that such should be the case, for the flavor of the truffle that is consumed by the chicken permeates the whole system, which it cannot do when simply placed in the carcass. M. Moular instances cases in which bares killed in a wormwood field, larks shot in a cabbage field, and eggs laid by hens which had eaten diseased silkworms, had such a nauseous taste that no one could touch them; while upon the other hand some ducks and hildfares which had fed upon sprigs of juniper had a delicious flavor. He has made several experiments—among others, three upon tame rabbits, which he fed with the waste of aniseed, with harley and bran containing a slight flavoring of juniper, and with harley and bran containing a little essence of thyme. In each case he found that the flesh of these animals was far better eating than that of rabbits fattened in the ordinary way, and yet that there was no trace of aniseed or juniper in the taste. His conclusion is that cattle, sheep and pigs might be fed in the same way, and that by varying the flavoring matter the beef, mutton and pork might be made to have several different tastes.—*Caterer.*

THE WONDERFUL ADAPTABILITY OF PAPER.—The adaptability of paper to numerous important and widely varied uses is wonderful. What other substance can be so satisfactorily substituted for wood, iron, and such common materials, to the extent that paper can be? It is impossible to find anything else which, like paper, may be so differently and dexterously prepared, as regards flexibility, thinness, strength, durability, imperviousness to fire and water, etc., that it can be readily made into pails, washbowls, dishes, bricks, napkins, blankets, barrels, houses, stoves, wearing-apparel, curtains, bonnets, newspaper and writing sheets, wrappers, carpets, coating for iron ships, flower-pots, boxes, parchment slates, coverings for the leads of pencils, jewelry, lanterns, car-wheels, dies for stamping uppers of shoes, roofing, and many other things. It is this tendency on the part of paper to take the place of everything else, to become a universal substitute, so to speak, which leads to the conclusion that the future has a grand development in store for it, and that in years to come its manufacture will hold a magnificent position among the great industrial interests of the world.—*Chicago Journal of Commerce.*

IMPROVED LAMPS.—Mr. Sugg, the well-known gas engineer, has lately devised a form of compound Argand burner for street and out-door uses. It is now in use in London on several of the prominent thoroughfares, and is highly commended. Several of these gas lamps give an illumination of 200 candle-power each. The same inventor has likewise devised a very ingenious self-ventilating gas lamp for the special use of libraries. It is provided with a chimney in the form of a metallic tube, which delivers the products of combustion out at the roof, or to some other convenient place outside of the library room. This flue is surrounded by a second larger cylinder communicating with the base of the lamp, which is closed, and through which the lamp receives its air supply also from the outside of the room. The lamp, therefore, neither impoverishes nor vitiates the air of the room. It was designed to meet the objection that the sulphurous gases evolved in the combustion of coal gas have a deleterious action on the leather of the book bindings.

IMMENSE DEPOSIT OF SODIUM SULPHATE.—The *American Journal of Pharmacy* notices the occurrence, in the Russian Caucasus, of two lakes which contain immense quantities of sodium sulphate, from which this salt is obtained in an almost pure state. The lakes have no exit, fill up in the wet season, and in summer their contents partially evaporate. The salt is obtained in layers of from a quarter to four inches thick, as it separates in consequence of cold or by evaporation in summer. Samples that were analyzed show that the dry salt contains 95% pure sulphate, of which it has been estimated the two lakes should yield 260,000 tons. It is further said that a French company has been formed to work this deposit systematically. Of the origin of the salt our informant gives no explanation.

TO CUT SHEET BRASS.—Moderately thick plate may be cut chemically by drawing a line or mark with a solution of mercury in nitric acid. The acid attacks the copper, while mercury amalgamates with the zinc; this seems to be the explanation; at any rate, the brass becomes as brittle as glass on the place where the line is drawn, and is easily broken off.

RED OAK AS AN ORNAMENTAL WOOD.—Red oak is found in abundance in almost all parts of the country, and from its plentifulness and its unsuitableness for a large majority of the commercial uses to which white oak is utilized, has been looked upon with a contempt, but little deserved when its adaptability to the manufacture of furniture is taken into consideration. It is more brittle than white oak and more porous, and this has probably been the cause of its neglect for shipbuilding purposes, combined with the fact that it is more susceptible to the attacks of the insect world which abound in salt water. It is not a wood which will stand the variations of wet and dry; and while white oak was to be had in abundance, the red oak was thought fit only to be made into flour barrels. When sawed bastard, so as to fully develop the grain, there is no question of its beauty being equal to black walnut, in the eyes of those who are not prejudiced in favor of the rich dark color of the latter.

INTERESTING IF TRUE.—Last week, says a late exchange, a man named Glyden, who was employed at the stove factory at Empire City, Oregon, came in contact with a buzz-saw, and one of his arms was cut entirely off just above the wrist. The unfortunate man had presence of mind enough to replace the severed member, but in his haste turned it so that the palm of the hand faced outwardly. This mistake was noticed at once by a fellow workman, and the arm was placed in its proper position, bandaged, and a physician being fortunately obtained, the flow of blood was stopped, and there is now a fair prospect that in a few months' time his hand will be as good as ever. Certainly a most wonderful escape.

HOW TO USE OIL-STONES.—Instead of oil, which thickens and makes the stones dirty, a mixture of glycerine and alcohol is used by many. The proportions of the mixture vary according to the instrument operated upon. An article with a large surface, a razor, for instance, sharpens best with a limpid liquid, as three parts of glycerine to one part of alcohol. For a graving tool, the cutting surface of which is very small, as is also the pressure exercised on the stone in sharpening, it is necessary to employ glycerine almost pure with but two or three drops of alcohol.

GOOD HEALTH.

Effect of Starvation on the Blood.

During the last hour of Dr. Tanner's 40 days' fast, some of his blood was withdrawn from the hand and subjected to a careful microscopic examination by Dr. P. H. Vander Weyde. It was found to be entirely different from healthy blood. The corpuscles, which are otherwise smooth and round flat disks, with a depression in the center, and of an average diameter of 1-3600th part of an inch, were found to be ragged, irregular and shrunk to the average of about 1-5000th part of an inch in diameter.

When blood is given time to dry on the microscope slide, the corpuscles may lose their smooth appearance and become smaller by shrinkage, but in this case there was no chance to be misled into error by such a cause, as the blood was examined while perfectly fresh and the corpuscles still moving freely in the plasma.

This ragged appearance was so common in all of them that there was scarcely a smooth corpuscle among them, except the white ones, which had very nearly the normal size and were smooth. Their number, which ordinarily hears to the red corpuscles the proportion of 1 in 400, was apparently increased. Occasionally the white corpuscles were seen clotted together in a way never observed in normal blood.

A further study of these abnormal red corpuscles showed that their rough appearance was generally caused by points projecting from their surface, and looking like a fungoid growth which covered them, while in many this growth appeared to be taking place at the expense of the corpuscle itself and living on its substance, as the corpuscles most densely covered were the smallest and the most irregular in shape; in fact some of them appeared disintegrating and breaking up.

We represent here some of the corpuscles as they appeared in the blood of Dr. Tanner, as seen and drawn by Dr. Vander Weyde, and at the side of the healthy blood the contrast is striking:

It is a common law observed in organic substances that when a breaking up of the structure is impending, foreign living organisms spring up, and are sustained at the expense of the decaying organic body. Mold, and all kinds of fungoid growth, originate according to this law, while in infusorial life it reaches its highest development. In the latter case it appears intended to economize the organic materials of the structure, and in place of allowing them to decompose into their primary elements, and to be built up again by the slow and laborious process of vegetation under the influence of light, these organic materials are directly transformed into food for the larger inhabitants of water, and finally for fishes.

rious process of vegetation under the influence of light, these organic materials are directly transformed into food for the larger inhabitants of water, and finally for fishes.

If the formation of fungoid spores, which is of a vegetable nature, also serves a useful purpose (which is probable), is as yet a question to be determined by further investigation; but certain it is that such a growth is not confined to large masses, but even found on the surface of such small objects as the corpuscles of the blood; this in fact has been recently investigated by microscopists, especially Koresl, and such growth was found upon the blood corpuscles of patients when seriously suffering from various malarial diseases, such as typhus fever, etc., also in the last stages of consumption; and they agree that this growth exerts a destructive influence upon the body in which it takes root.

The appearance of Dr. Tanner's blood verifies this opinion. Very few, if any, corpuscles were free from the fungus, and all appeared to have suffered and shrunk in size, while many of them had become irregular in shape, and evidently were breaking up. As it appears to be the function of the liver to secrete the effete blood corpuscles, the liver of Dr. Tanner must have been taxed greatly, and this would explain his hitherto suffering during the latter stages of the fast, when he often vomited bile with the mucus of his stomach.

In regard to the latter its digestive powers are phenomenal. Immediately after breaking the fast at the exact hour that the 40 days were ended, by eating a peach, he drank successively two large glasses of milk, ate half a watermelon, two beefsteaks, five apples, drank Hungarian wine, and had a good time generally, and was the next day already in good condition, gaining at the rate of five pounds weight every 24 hours.

The effect on the blood was very perceptible only 24 hours after breaking the fast. The fungoid spores had disappeared from a great many of the blood corpuscles, or, rather, perhaps, fresh ones had been evolved in the system, which is the most probable, as they looked as smooth and fresh as if they were entirely new. At the second day about half of the blood had become normal, while on the third day most all the corpuscles were restored; however, there were here and there still some imperfect ones, irregular in shape, as if they were remnants, and even some of these were not yet entirely free from the fungoid growth.

Powers of endurance have been exhibited by various individuals, but we believe none have ever gone through such severe and well authenticated test of physical endurance as Dr. Tanner, to whom at least the credit should be given to have practically demonstrated what man can endure when he, to use Dr. Tanner's own words, "once understands his own machinery and knows how to run it."—*Scientific American.*

Pertinent Facts About Eating.

In a recent number of the *London Standard* under the query, "do we eat too much?" the writer gives many interesting facts. He says, for instance that the amount of nourishment which a person needs greatly depends on his constitution, state of health, habits and work. A sedentary man requires less than one whose duties demand the exercise of his muscles, and a brain-worker needs more than an idler. But unquestionably the majority of us take more than we need. Indeed, food and work are distributed most unequally. The man of leisure is also the man of means, and accordingly, fares sumptuously every day; while the laborer toils for eight hours, and finds it difficult to get enough to repair the waste of his tissues. Yet a Chinaman or a Bengalee will toil under a tropical sun, and find a few pice worth of rice or jowrah sufficient to sustain his strength. A Frenchman will not eat half what an Englishman engaged in the same work will demand, and a Spanish laborer, content in ordinary times with a watermelon and a bit of black bread, will toil in the vineyards and grow fat on a dietary of onion porridge and grapes. It is true that Mr. Braesey, when building the Continental railway, found that one English navy was worth a couple of spare-fed foreigners. But, on the other hand, the British Columbian and Californian gold-diggers, than whom a more magnificent set of athletes does not exist, live in the remote mountains of the Far West mainly on beans flavored with a few cubes of pork. But they also obtain the beet of water and the purest of air, and their out-door life and active exercise enable them to digest every ounce of their frugal fare. The English soldiers, though better fed than those of any army except the American, do not get one-half the amount of solid nutriment which the fittest of club-loungers considers indispensable for his sustenance. An athlete in training is allowed even less food; yet he prospers on the limited fare, and prolongs his life by the regimen by which he has been subjected. King Victor Emmanuel was a monarch of the most robust physique; yet he only ate one meal per day, and it is manifestly absurd for any man to require three more or less weighty meals, and an afternoon cup of tea, to support the exertion of walking to the club, riding an hour in the park, writing a note or two, and dancing a couple of miles around a ball-room. The ancients had their "amethusetois," or "sober stones," by which they regulated their indulgence at table. The moderns have not even this. But they have their gout and their liver to warn them, when it is too late, that nature has been overtaken.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—A New Submarine Torpedo; Petroleum as Fuel; The True Concentrator; A Volcano Rising from a Lake, 161. The Week; The Tendency to Cities; "The Microscopist," 162. Notes on Some Sierra County Mines; The Silkworm Cocoon and Moth, 169. Notices of Recent Patents; The Pacific Coast Steamship Co.; Mechanics' Fair Notes, 172. ILLUSTRATIONS.—The True Concentrator, 161. Silkworm, Cocoon and Moth, with Cocoons of Different Varieties, 169.

CORRESPONDENCE.—Aaron Process, 168. METEOROLOGICAL.—Mountain Lakes of the Sierra Nevada, 162.

MISCELLANEOUS.—Interesting Facts About Iceland; The Famous Horn Silver Mine; The Law of Mutual Help, 162. Subterranean Kaolinization—The Comstock Lode; The Gatling Gun; A French Co-operative Scheme; Measuring the Velocity of Light, 167. Explosive Mixtures of Air and Gas; A Remarkable Case of Somnambulism, 170.

MECHANICAL PROGRESS.—Steel for Boilers; Chain Fire-Grate Bars; Electro-Motors of the Future; Fire-Resisting Qualities of Building Stone; An Improved Electric Motor, 163.

SCIENTIFIC PROGRESS.—American Astronomical Work; Thin Rolled Iron for Scientific Purposes; Danger in Toughened Glass; A Table Land Across the Gulf Stream, 163.

MINING STOCK MARKET.—Sales at the San Francisco Stock Boards, Notices of Assessments, Meetings and Dividends, 164.

MINING SUMMARY from the various counties of California, Nevada, Arizona and Idaho, 164-165.

THE ENGINEER.—This Belgian Cable System on the Erie Canal; New Developments in the Mississippi River Improvements, 167.

USEFUL INFORMATION.—The Flavor of Meat; The Wonderful Adaptability of Paper; Improved Lamps; Immense Deposits of Sodium Sulphate; Red Oak as an Ornamental Wood, 167.

GOOD HEALTH.—Effect of Starvation on the Blood; Pertinent Facts About Eating, 167.

NEWS IN BRIEF on page 172 and other pages.

The Week.

The most interesting event of the week has been the arrival in this city of the President of the United States. The incident is sufficiently novel and gratifying to awaken the liveliest enthusiasm of our people; for it is the first time in the history of the State that the Chief Magistrate of the Union has visited the far-off shore of California. President Hayes has been welcomed with a genuine warmth of feeling; for apart from his exalted official station, which is not surpassed by that of King or Kaiser, his fellow citizens recognize in him the upright and estimable American gentleman. His journey hither has been marked by the most cordial respect from the entire body of the people. While reflecting upon these things one cannot help thinking of a recent journey through his dominions of a foreign potentate, surrounded by thousands of armed men, and other thousands of the emissaries of a sleepless police, to shield his majesty against hundreds of eager assassins among his own subjects.

Since our last issue the Freeholders' Charter for this city has been submitted to a vote of the people at a special election, and was rejected by an overwhelming majority. The vote was very light, amounting to only 23,352, of which number 19,270 were against the charter, and 4,145 for it. It is a most decisive vote.

The news from the mining counties of this State is very satisfactory. Many of the hydraulic claims have cleaned up for the season, and are now busy with preparations for the next rainfall. The yield of gold has been fully up to the average season. For a detailed account of mining operations in every State and Territory on the coast, we refer the reader to our comprehensive "Mining Summary."

A PROMISING MINE.—The Salt Lake Tribune, of the 5th inst., says the December G. & S. M. Co. of Lincoln district, Beaver county, has just made its first shipment of ore, amounting to about 10 tons, from the December mine. The ore sampled as follows: First class, 47% lead, \$166.11 in silver; second class, 39% lead, \$117.64 (91.2 ounces) silver and \$6 in gold; third class, 12.5% lead, 56.37 (43.7 ounces) in silver and \$6 in gold. The whole shipment thus averaged about \$100 in gold and silver, and 33% lead.

The Tendency to Cities.

The census which has just been taken shows an increasing tendency of the population towards cities. We have become, as an Eastern writer has remarked, "a nation of cities." Our people apparently have long since disregarded the monition that "God made the country and man made the town." Whatever may be the cause, we are building up cities more numerous and rapidly than any other people ever did. The cause of this tendency does not lie upon the surface, and is more or less complex; but we think it may be explained in part by the operation of the "law of mutual help"—the instinct which impels men to desire a closer association and co-operation for their mutual comfort and advantage. As men advance in civilization they become more gregarious; and the advantages and fascinations of city life are many and great. But there must be some necessity which impels men to move toward common centers.

The late census was not needed to show that the drift of population in this country was towards cities. From 1860 to 1870 the urban population increased faster than the rural in all the settled states of the North. Several of the Eastern papers have given exhibits of the tendency of our population, as shown by the census returns, since 1860; but the best that we have seen is in the Springfield *Republican*, and as that journal is unusually careful and trustworthy we will use its figures. They show that the city population of the United States is not only increasing faster than its agricultural population, but that it has reached a point at which its relative share of the population of the country is equalled in Europe only by Great Britain, while the number of its cities is equalled by no other country. The list of cities, though incomplete, shows an aggregate urban population of 8,203,238. The same cities in 1870 had a population of 5,039,490, showing an increase in 10 years of 3,163,748, or 62%. During the same interval the population of the country has advanced less than one-half as fast, or at the rate of 25%. There is no doubt that the complete returns of all the cities of the country will give them a population of over 9,000,000. Of this large total, between 7,000,000 and 8,000,000 are to be found in cities containing upwards of 50,000 inhabitants. At the lowest estimate, from one-fifth to one-sixth of the population of the country is now living in its cities, and this in a population of about 48,000,000, whose farmers in the West supply the world largely with food, while those in the South supply it with cotton.

In Massachusetts, New York, Illinois and Ohio, there has been a large increase in the urban as compared with the rural population. In Illinois and Ohio the chief increase is due to their cities, as in both states there are counties which show a decrease of population. The cities of the South show a comparatively light increase; and on the Pacific coast the increase in city and country has been about equal, although many of the cities, notably San Francisco and Oakland in this State, show a large increase in their population. In the great and prosperous States which lie between the Atlantic and the Mississippi, north of the Potomac and the Ohio, the increase of population is due chiefly to the growth of great cities. It has been estimated that within the area designated five-sixths of the urban population of the country will be found. It is apparent that the tendency of our population is towards cities. In a table published by the *Republican* there is a list of 106 cities in which the population ranges above 30,000 and above 1,000,000. Of the number, 1 has a population above 1,000,000, 1 above 750,000, 2 above 500,000, 5 above 300,000, 1 above 250,000, 2 above 200,000, 3 above 150,000, 7 above 100,000, 4 above 75,000, 11 above 50,000, and 69 above 30,000.

The *Republican* mistakes greatly, we believe, when it says that the experience of Cincinnati, St. Louis, New Orleans and San Francisco "indicate, without absolutely proving, that at many centers American cities have reached substantially their full growth." On the contrary, we believe that all the facts presented by the relations of the four cities mentioned indicate that they have not nearly reached their full growth. Certainly, so far as San Francisco is concerned, the facts of the late census do not warrant the conclusion. For, after several years of extraordinary depression, during which the population was thinned by thousands, she shows an increase in 10 years which is surpassed by few cities in the country. The city is recovering her prosperity slowly but surely, and it appears entirely safe to predict that its population will largely increase—we believe it will double itself—before the expiration of the present decade.

A MINE SUIT SETTLED.—The vexatious and long-pending difference between the Justice Mining Company and Schultz & Von Bargen has at last reached a satisfactory settlement. On Tuesday all the pending actions between the parties were dismissed in Judge Evans' court. The business has been well settled, to the advantage, we believe, of the shareholders of the Justice, for the continued litigation was good for neither mine nor shares.

"The Microscopist."

We have before us the fourth edition of "The Microscopist," which, it is but truthful to say, is one of the most complete and comprehensive works on microscopy extant. The publishers, Messrs. Lindsay & Blakiston, of Philadelphia, have spared no pains in giving the work a neat typographical appearance, and no expense in embellishing it with a profusion of well-executed and most faithful illustrations in each of the several branches of study to which it is devoted. This edition has been enlarged by the addition of over 200 pages of entirely new matter, devoted to Pathology, Diagnosis, and Etiology, illustrated with wood-cuts from Rindfleisch. A full index and glossary have also been combined in this edition, which, together with notices of recent additions and improvements to the microscope, will be found a source of much valuable information to the microscopist.

The work, as it now appears, is a perfect manual of microscopy and a full compendium of microscopic science in all of its leading branches of mineralogy, chemistry, biology, histology and medicine. No physician, at the present day, can be considered well up or can keep up with his profession, without practical knowledge of the microscope and microscopic science. To the student of physical phenomena, a knowledge of the minute structures of the universe is quite as essential as the study of those grander aspects of nature which are shown forth in the heavens or spread out upon the surface of our earthly sphere. In the arts also, as well as in scientific investigations, the microscope now finds a most needful and conspicuous place. The jeweler, the engraver, the miner, the man of commerce and, in particular, the agriculturist and horticulturist must make more or less use, and have more or less knowledge of the microscope, either as a simple or compound instrument.

It is to Dr. J. H. Wythe, of Oakland, that the public is indebted for this most valuable work, and we trust it may be the means of adding largely to the grand army of true and earnest workers already engaged in the various fields of microscopic research. We speak from personal knowledge when we say that the Doctor is a modest and unpretending, yet a rare and most enthusiastic worker in this interesting field of science; and that he works for the love of it and for the good that may grow out of it, rather than from any hope of pecuniary reward. "The Microscopist" is for sale at the bookstores generally, price \$5, neatly bound in cloth.

FAST HYDRAULIC SCHEME.—We learn that a remarkably bold mining project is in contemplation by a party of California hydraulic miners. It is no less than to dig a tunnel on Feather river, commencing at Whiskey Bar, on the northern end of the Big Bend, at a point about three miles from Yankee Hill to Island Bar, on the southern end of the Big Bend. This tunnel is to run under the Big Bend mountains about two and a half miles, and is to be capacious enough to turn the water of Feather river so that the entire bed of the river between those points can be worked. The *Chico Enterprise* says a company with ample means has been formed to carry out the bold scheme; and that a surveyor is now engaged in making a survey of the route of the proposed canal. The length of ground that can be worked, if the river is successfully turned, is over 12 miles, and no part of the mining region in this county has given better prospects than the whole of Big Bend. For many a long year the Feather river has flowed through this ancient channel, which is nothing less than a natural sluice, and the quantity of gold that lies embedded in its hidden recesses must be incalculable. The project is a bold one, yet seems feasible. There are no difficulties apparent in the way of running the tunnel, and when once completed, so that the water is carried through the short cut of two and a half miles, the work of washing the enormous mass of pay dirt will be simplicity itself.

A THRIVING MINING CAMP.—Rich discoveries continue to be made in El Dorado canyon, San Bernardino county. A correspondent of a San Bernardino paper, writing from that camp, says: We have visitors who desire to hound our mines, but as long as we are taking out rich ore and plenty more in sight, we want to see the cash if we dispose of our claims. We struck an 18-inch ledge of ore that assays \$416 per ton. A contract has been let on the Silver Eagle to run a tunnel 50 ft. Work has been commenced on the January mine. The ledge is from 6 to 40 ft. wide. The ore so far taken out assays from \$100 to \$300 per ton. Men are arriving here every day, and I believe there will be a camp of 500 men here in less than two months. Mr. Philie, the Raymond & Ely Superintendent, has returned from California. He has bonded a mine for \$10,000 and will commence work on it immediately. Weaver is still sinking on the Lone Star mine, and taking out ore that mills about \$1,000. The streak is only eight inches wide. Nichols, Howell and Warneke are at work on their claim, and are taking out horn silver ore that so far has assayed \$5,860 per ton.

Aaron Process.

EDITORS PRESS:—It has recently been found that the quartzite ores of the Diana mine, near Beaton, in Mono county, can be worked very satisfactorily in iron pans without roasting, a result which I freely confess somewhat surprises me, as Mr. Millet, of the Comanche mill, tried it only a few years ago without much success. I attribute the improvement to the relatively new practice of working the pans without grinding the ore in it, as I am pretty sure it could not be done in the old way.

It is well known that, 11 years ago, I introduced at Benton a process of working those ores in a barrel, to which process I had the temerity to attach my name, not because it was essentially new, but as explained in all my writings and conversations about it, particularly in my little book on "Testing and Working Silver Ores," because of certain modifications and improvements which I made, and because I introduced successfully a process, which, in its original barbarous form, would never have been used in this country.

The process continued to be used at Benton till quite recently, but now that it is superseded by an improved system of pan work, I receive the enclosed flattering notice from the *Weekly Bentonian*, which at least shows that the editor of that paper has not been a diligent reader of the MINING AND SCIENTIFIC PRESS, or he would hardly accuse me of affecting secrecy or mystery about my work.

C. H. AARON.
Editor *Bentonian*.—DEAR SIR: Was not the "barrel process" used in the Diana mill, of which you wrote some what disparagingly in the last *Bentonian*, a recent discovery and was not the inventor Charles H. Aaron, who at one time had charge of some of the mills around this camp, the Diana included? and is it not known as "Aaron's Process?"—INQUIRER, Benton, August 26, 1880.

No, sir. The barrel process of amalgamating ores was discovered, perfected, and put in use by Father Cascastades, a Spanish priest, in one of the Mexican States, in the year 1721. If you can borrow a slate and a short pencil, and if you are anyways apt at figures, you can ascertain, in the course of an afternoon's mental calculations, that this was probably some years prior to the birth of Charles H. Aaron, and that it was even before the discovery of mines on Blind Spring hill. This was the first known process of amalgamating ores ever discovered, so far as the encyclopedias furnish any information. "Aaron's process" consisted in being so mysterious with his chemicals and his barrel as to impress his employers with the belief that he was in possession of some valuable secret in connection with amalgamation, thus always securing to Charles H. Aaron a good fat situation. So far as we can ascertain Mr. Aaron is entitled to no credit in regard to the workings of the barrel process.

Fairs and Horses.

Now that the State fair is about to open, with its exhibits and displays of the industry and products of field and farm, garden and orchard, etable and barn, it is well perhaps to say a word about the chief business, or rather the chief events, of such gatherings. That is, pure and simple—horse. And if it shall be the trotting horse, we say amen to the mauly pastime. One cannot easily forget the clear-headed wisdom of the ever-delightful Autocrat of the Breakfast Table: "Wherever the trotting horse goes, he carries in his train brisk omnibuses, lively bakere's carts—and therefore hot rolls—the jolly butcher's wagon, the cheerful gig, the wholesome afternoon drive with wife and child—all the forms of moral excellence except truth, which does not agree with any kind of horseflesh." This is a sad judgment on trotters, for even that noble animal has been taught by the yahoos of the stable that "evil communications corrupt good manners." Yet, in the main, the just Autocrat is sound on the trotter. Hear him: "Horse racing is not a republican institution; horse trotting is. Now just compare the racer with the trotter for a moment: The racer is incidentally useful, but essentially something to bet upon. The trotter is essentially and daily useful, and only incidentally a tool for sporting men." Here is a fine distinction and a radical difference; and it is not the fault of the trotting horse if it is not as true now as when it was spoken. The trotting horse is essentially a republican institution. The masses want trotters, and are best served by them. Therefore, gentlemen of the State fair, give us horse and plenty; but by all means let it be the trotting horse.

A COLLIERY HORROR.—Dispatches from London say that a terrible explosion occurred on the evening of September 8th in the Seaham colliery, in Durham county, on the North sea. At the time of the explosion, it is estimated that from 180 to 250 men were in the pit. The latest news is that a total of 66 men had been rescued in an exhausted condition. So far there is no sign of fire, but it is evident there is a large accumulation of gas. Two corpses have been brought to the surface, one of which was badly burned. The greatest excitement prevails in the neighborhood of the colliery, and the frantic cries of the wives and children of the imprisoned men are represented as terrible.

Notes on Some Sierra County Mines.

[The gravel claims of Brandy City, Scales' Diggings, Port Wine, St. Louis, Howland Flat and Gibsonville. Compiled from the Sierra Free Press.]

Brandy City.

This town is surrounded on all sides by large canyons, and receives its supplies on mules and Chinamen. It has a population of 150, besides a large number of Chinese. The mining season just closed has been the shortest one for years, and is due to the fact that a snowslide carried away some 1,500 boxes of the Hoosier ditch, from which the mining companies get their water.

The Brandy City hydraulic mine is represented to be one of the richest in the county. It was located about 26 years ago, and since that time has yielded millions to its owners. The company has ground enough to last it for many years to come. The water gave out about three weeks ago, and the company has just finished cleaning up. About 15 men are now employed running powder drifts and extending the main flume, and getting ready for the coming season.

The Arnott claim, about a quarter of a mile east of the town, has closed work for want of water, and the owners are now cleaning up. During the season a large ore of ground has been washed, and the yield, so far as known, has been satisfactory. The claim employs a number of men the year round.

The Grizzly claim, about a mile south of town, has closed down and cleaned up. This claim has always paid well, and as the last run has been a long one, it is presumed the result has been good.

The Bunker Hill Co. is about four miles north of Brandy City, and is a drift gravel claim. The company is running a bedrock tunnel, with flattering prospects. The owners, a body of hard-working miners, have already expended a considerable sum of money on their ground.

Scales' Diggings.

This camp lies about seven miles northwest of Brandy City, and is reached by one of the roughest, steepest, crookedest trails in northern California. It is somewhat larger than Brandy City, and, in common with the mining town of Sierra county, it boasts of a brass band.

Among its mines, the Cleveland Co., half a mile below town, is making good progress. It gives employment to about 50 men during the water season, and about a dozen the remainder of the year. The company has just cleaned up, and is preparing for the next season. The ground is very rocky, and has been worked over twice, and must be extremely rich to justify the outlay of the present owners.

Union Hill claim has just closed for want of water. The season has been unusually short, as work was not begun until the middle of May. A few men will be kept at work running bedrock cuts and powder drifts. On the same lead, about a mile to the southward, is the Fairplay Co. It is one of the oldest mines in Scales' Diggings, and has always paid good dividends to its owners. The company has just cleaned up for the season, and will shortly resume work for the coming season.

Poverty Hill claim, a drift mine, about three miles north of town, is one of the most productive properties in the vicinity of Scales'. For several years the dividends from this mine have averaged \$50,000. The company has just finished cleaning up, with a handsome result.

St. Louis.

This little town, which ought to be called Phenix, has been burned some 13 times since 1853. It has a population of less than 100 whites, and a large number of Chinese.

The Donahue claim, about half a mile east of town, is the most important mine in the camp. During the season of water it gives employment to 125 persons, a large part being Chinese. The company has worked a large area of ground this season, and is now cleaning up. A short distance below the town are some drift gravel claims, from which the owners are getting good pay. The work in these mines is done principally by Chinese.

Gibsonville.

This town is just recovering from the recent fire, which nearly swept off all its buildings, both business and residence.

About a mile and a half east of the town the Niagara Con. Company is working in its lower tunnel, some 2,000 ft. long. The upper tunnel is 3,000 ft. long, and is still pushing ahead. The company employs about 50 men. It has lately finished a satisfactory clean-up. On the Michigan claim, on which the owners have been at work about seven years, they are still driving the main tunnel, which is some 3,000 ft. long, and expect to tap the channel in the course of 150 ft. The Union company is also a drift claim, with a tunnel about 2,500 ft. long. During the past year the company has breasted 1,200 ft. at the mouth of the tunnel. It has recently finished cleaning up, and will resume work on the main tunnel.

The Gravel Hill claim, about a half mile east of town, is an important property. The company has cleaned up for the season, having washed much less gravel than usual. The mine is in good condition for the coming season, however, and the bedrock cut is deep enough for several years' work. The company works

about 40 hands, and uses 3,000 inches of water. Two powerful monitors work night and day during the water season. The pressure is 200 ft., and as the gravel is free, an immense body is washed during a run of 100 days. The company owns three water ditches, one of which is four miles long, and has a large tract of land.

There is also the Squire claim, a drift gravel mine with a tunnel about 1,000 feet long, from which the owners are taking gravel worth \$1 to the car load, and have water enough to wash the year round. The somewhat famous Boot-jack gravel claim has been closed for some time on account of the volume of water; but there is a good prospect that it will be re-opened shortly. And the Horace Taber claim, also closed, is about to resume work.

Howland Flat.

This is the largest town in the northern part of the county, and boasts of two hotels. Among the population there are nearly 400 Chinese, who are mainly employed in the mines.

The Virginia claim at Potosi, about half a mile from the town, is an incorporated company. It has a tunnel 2,500 feet long. The late clean-up of the company averaged \$5 to the car load. The ground is soft, and the owners expect to strike much richer gravel in a short time.

The claim of Chittenden, Jackson and Small, a short distance below the town, is conceded to be the richest hydraulic property in the vicinity. The owners have been at work during the year on a bedrock tunnel, 22 feet lower than the old one, which will give them a considerable area of new ground. They have just finished the season's clean-up.

The Bonanza claim is situated just above the Virginia, and adjoins the celebrated Keystone mine. Work was begun in the tunnel about two years ago, and last January pay gravel was struck, since which time over \$6,000 have been taken out. The work is carried on by two shifts of 20 men each.

At the claim of Cox & Co., they have cleaned

The Silkworm Cocoon and Moth.

Now that the silken industry seems fairly given over to our sisters, our cousins and our aunts, and the burden of developing the possibilities of sericulture in this country has been accepted by them, the subject takes on new interest. The new phase of the old problem will no doubt attract the attention of many who do not know the difference between a silkworm and a tent caterpillar, and we have thought it timely to give engravings of a common species of silkworm cocoon and moth, with brief descriptions of the transformations of the insect. We take these mainly from the writings of Prof. C. V. Riley, who is a firm believer in household silk culture.

The egg of the silkworm moth is called by silk-raisers the "seed." It is nearly round, slightly flattened, and in size resembles a turnip seed. Its color when first deposited is yellow, and this color it retains, if unimpregnated. If impregnated, however, it soon acquires a gray, slate, lilac, violet, or even dark green hue, according to variety or breed. It also becomes indented. As the hatching point approaches, the egg becomes lighter in color, which is due to the fact that its fluid contents become concentrated, as it were, into the central, forming worm, leaving an intervening space between it and the shell, which is semi-transparent. Just before hatching, the worm within becoming more active, a slight clicking sound is frequently heard, which sound is, however, common to the eggs of many other insects. After the worm has made its exit by gnawing a hole through one side of the shell, this last becomes quite white. Each female produces on an average from 300 to 400 eggs, and one ounce of eggs contains about 40,000 individuals. It has been noticed that the color of the albuminous fluid of the egg corresponds to that of the cocoon, so that when

days more, by a final molt, into the chrysalis state.

The cocoon, Fig. 2, consists of an outer lining of loose silk, known as "floss," which is used for carding, and is spun by the worm in first getting its hearings. The amount of this loose silk varies in different breeds. The inner cocoon is tough, strong, and compact, composed of a firm, continuous thread, which is, however, not wound in concentric circles, as might be supposed, but irregularly, in short figure of 8 loops, first in one place and then in another, so that in reeling several yards of silk may be taken off without the cocoon turning round. In form, the cocoon is usually oval, and is color yellowish, but in both these features it varies greatly, being either pure silvery-white, cream or carmineous, green, and even roseate, and very often constricted in the middle.

The chrysalis is a brown, oval body, considerably less in size than the full-grown worm. In the external integument may be traced folds corresponding with the abdominal rings, the wings folded over the breast, the antennae, and the eyes of the inclosed insect—the future moth. At the posterior end of the chrysalis, pushed closely up to the wall of the cocoon, is the last larval skin, compressed into a dry wrad of wrinkled integument. The chrysalis state continues for from two to three weeks, when the skin bursts and the moth emerges.

The moth is shown in Fig. 3. With no jaws, and confined within the narrow space of the cocoon, the moth finds some difficulty in escaping. For this purpose it is provided, in two glands near the obsolete mouth, with a strongly alkaline liquid secretion, with which it moistens the end of the cocoon and dissolves the hard, gummy lining. Then, by a forward and backward motion, the prisoner, with crimped and damp wings, gradually forces its way out, and when once out the wings soon expand and dry. The silken threads are simply pushed aside, but enough of them get broken in the process to render the cocoons from which the moths escape comparatively useless for reeling. The moth is of a cream color, with more or less distinct brownish markings across the wings, as in Fig. 3. The males have broader antennae or feelers than the females, and may by this feature at once be distinguished. Neither sex flies, but the male is more active than the female. They couple soon after issuing, and in a short time the female begins depositing her eggs, whether they have been impregnated or not.

Domestication has had the effect of producing numerous varieties of the silkworm, every different climate into which it has been carried having produced either some change in the quality of the silk, or the shape or color of the cocoons, or else altered the habits of the worm. Some varieties produce but one brood in a year, no matter how the eggs are manipulated; such are known as *Annals*. Others, known as *Bivoltins*, hatch twice in the course of the year; the first time, as with the *Annals*, in April or May, and the second, eight or ten days after the eggs are laid by the first brood. The eggs of the second brood only are kept for the next year's crop, as those of the first brood always either hatch or die soon after being laid. The *Trevoltins* produce three annual generations. There are also *Quadrivoltins*, and, in Bengal, a variety known as *Dacey*, which is said to produce eight generations in the course of a year. Some varieties molt but three times, instead of four, especially in warm countries and with *Trevoltins*. Experiments, taking into consideration the size of the cocoon, quality of silk, time occupied, hardness, quantity of leaves required, etc., have proved the *Annals* to be more profitable than any of the *Polyvoltins*, although *Bivoltins* are often reared; and Mr. Alfred Brewster, of San Gabriel, Cal., says that he found a green Japanese variety of these last more hardy than the Chinese *Annals*. Varieties are also known by the color of the cocoons they produce, as greens, or whites, or yellows, and also by the country in which they flourish. The white silk is the most valuable in commerce, but the races producing yellow, cream-colored or flesh-colored cocoons are generally considered to be the most vigorous. No classification of varieties can be attempted, as individuals of the same breed exported to a dozen different localities would, in all probability, soon present a dozen varieties. The three most marked and noted European varieties are the *Milaoese* (Italian) breed, producing fine, small yellow cocoons; the *Arche* (French), producing large yellow cocoons; and the *Brousse* (Turkish), producing large white cocoons of the best quality in Europe. Owing to the fearful prevalence of *pebrine* among the French and Italian races for 15 or 20 years back, the Japanese *Annals* have come into favor. The eggs are bought at Yokohama in September, and shipped during the winter. There are two principal varieties in use, the one producing white, and the other greenish cocoons, and known respectively as the *White Japanese* and the *Green Japanese Annals*. These cocoons are by no means large, but the pods are solid and firm, and yield an abundance of silk. They are about of a size, and both varieties are almost always constricted in the middle (Fig. 4, c, green, d, white.) Another valuable race is the *White Chinese Annual* (Fig. 4, e), which much resembles the *White Japanese*, but is not as generally constricted. Fig. 4, a and b, represent, respectively, *White* and *Yellow French Annals*.

The heir of the Spanish throne will be baptised in water from the river Jordan, presented in a bottle, for that purpose, by M. Montilla, the Spanish Minister at Constantinople,

SILKWORM, COCOON AND MOTH, WITH COCOONS OF DIFFERENT VARIETIES.

up for the season, and are pushing work for the next. At Poker Flat—which has been made famous by Bret Harte—there is an hydraulic mine worked by four partners. They are cleaning up, and expect to realize \$4,000 each from the last run.

Port Wine.

This town, with the suggestive name, has a population of 100 persons, and has four saloons and three hotels. The water supply failed a short time since, and the miners are busy with their clean-ups. One of these, the Indian Queen, a short distance east of the town, employs 20 men. At Wahoo camp, across the ridge from Port Wine, several gravel mines are operating on a small scale.

DEVASTATION OF A BUSH FIRE.—A dispatch from a village in the Province of Quebec, Upper Canada, of September 8th, says a terrible fire took place there on Monday and carried ruin and death in its track. Bush fires have been numerous for some time, and little attention was given to them. The high wind Monday fanned the flames until the inhabitants, about 6 o'clock, saw with dismay a wall of flames come toward them with steady sweep, as fast as a man could run, and swallowing up everything in its course. By 4 o'clock the first farmhouse had been reached, and the fire ran along the rail fences burning grain, and the wind sent sparks in all directions. So quickly was one farmhouse and another enveloped, that men, women and children had barely time to escape out of its line. As night grew on the flames increased in volume, while the wind rose, and for a space of about 12 miles in length and in width from 3 to 4 miles, the eye rested upon nothing but roaring flames. About 75 families, representing 450 persons, have been burned out. Four persons are known to have been burned, and a large number is missing. The loss is estimated at \$300,000. The disastrous fire was caused by a farmer who was burning stubble.

NOT SO SMALL.—In an advertisement in last week's PRESS of a pumping engine for sale by Manuel Eyre, it was stated that the cylinder was 1-inch and stroke 6-inch. The true dimensions are 16-inch cylinder; 6-inch stroke. The advertisement in correct form may be found in this issue.

the fluid is white the cocoon produced is also white, and when yellow the cocoon again corresponds.

The larva, or worm, is shown in Fig. 1. The worm goes through from three to four molts or skinchanges, the latter being the normal number. The periods between these different molts are called "ages," there being five of these ages, including the first from the hatching and the last from the fourth molt to the spinning period. The time between each of these molts is usually divided as follows: The first period occupies from 5 to 6 days, the second but 4 or 5, the third about 5, the fourth from 5 to 6, and the fifth from 8 to 10. These periods are not exact, but simply proportionate. The time from the hatching to the spinning of the cocoon may, and does, vary all the way from 30 to 40 days, depending upon the race of the worm, the quality of the food, mode of feeding, temperature, etc.; but the same relative proportion of time between molts usually holds true.

The color of the newly hatched worm is black or dark gray, and it is covered with long, stiff hairs, which upon close examination will be found to spring from pale-colored tubercles. Different shades of dark gray will, however, be found among worms hatching from the same batch of eggs. The hairs and tubercles are not noticeable after the first molt, and the worm gradually gets lighter and lighter, until, in the last age, it is of a cream-white color. When full grown it presents the appearance of Fig. 1. It never becomes entirely smooth, however, as there are short hairs along the sides, and very minute ones, not noticeable with the unaided eye, all over the body.

Having attained full growth, the worm is ready to spin up. It shrinks somewhat in size, voids most of the excrement remaining in the alimentary canal; acquires a clear, translucent, often pinkish or amber colored hue; becomes restless; ceases to feed, and throws out silken threads. The silk is elaborated in a fluid condition in two long, slender, convoluted vessels, one upon each side of the alimentary canal. As these vessels approach the head they become less convoluted and more slender, and finally unite within the spinneret from which the silk issues in a glutinous state and apparently in a single thread. The glutinous liquid which combines the two, and which hardens immediately on exposure to the air, may, however, be dissolved in warm water. The worm usually consumes from three to five days in the construction of the cocoon, and then passes, in three

Explosive Mixtures of Air and Gas.

The recent explosions of gas in England, and notably the serious one in London, have naturally drawn attention to the question what admixture between gas and air is most strongly explosive. It appears that there is some conflict of opinion on the subject. According to the report in the London *Times*, it was stated by Mr. Foster, the chemist, at the inquiry respecting the death of the men who were killed by the gas explosion, that "the maximum admixture to make an explosion would be one part of gas to eight parts of air, and this would compose the admixture which exploded on Monday, the 5th ult., while one part of gas to seven parts of air would make a less explosive mixture." It is not to be supposed that all chemists would agree with Mr. Foster in these proportions. The ratio between air and gas to form an explosive mixture is more generally supposed to be 1 in 10. The subject was investigated at great length before a committee of the House of Commons in 1867, when the Metropolitan Board of Works introduced their Subways bill. Some of the first chemists and gas engineers were examined. Dr. Frankland, in his evidence, said that 1 part of gas to 10 of atmospheric air constitutes the most explosive compound, the lowest mixture which it is possible to explode being 6.6% of gas. This mixture ceases to be explosive and becomes combustible when in the proportion of one to four or four and a half, according to the quality of the gas. Mr. Forster, the mining engineer, who was opposed to the bill, stated that he found, from experience, that the most explosive mixture was about eight or nine volumes of air to one of gas, but in another part of his evidence the proportion is said to be one to seven or eight. Mr. H. E. Jones, the gas engineer, considered that from 10 to 12 would be most destructive, but Mr. R. Jones said that there would be nothing dangerous up to one in five; it would be dangerous at one in nine, and very dangerous at 1 in 10. Mr. Bramwell, who made experiments of every proportion, was of opinion that about 10% is the maximum of explosiveness, but if it amounted to 20%, an explosion would no longer take place. When the gas becomes a fourth part of the air, the possibility of explosion ceases. —*Iron Age*.

A WONDERFUL BLIND MAN.—James Goodsell, who had been blind from his birth, died recently in Burlington, Conn. His wonderful career is thus sketched by the *Waterbury American*: In early childhood, however, Mr. Goodsell said that the darkness was in a few instances broken by faint glimmerings of light. Of four children, he and a sister were blind; the others could see. The sister, though at first possessed of ordinary vision, soon by a mysterious change became wholly deprived of sight. In absolute darkness, this ordinary employment of work-a-day life would seem impracticable, but this blind man would swing an axe with the dexterity of a woodsman, and actually felled trees; he was an accomplished grain thrasher, and would frequently go alone a distance of two miles to thresh for the Burlington farmers, climbing the mows to throw down the grain; he could hoe corn or garden stuffs as good as anybody, having no trouble to distinguish the weeds. He could set a hundred bean poles with more accuracy than most people who could see; would load hay beautifully, and was so good a mechanic that he manufactured yokes and other farm articles with success. He had an excellent memory, and was an authority on facts and dates. He could generally tell the time of day or night within a few minutes. One instance is given when he slept over one day and woke at evening, thinking it was morning. For once he ate supper for breakfast, but when informed of his mistake he slept another 12 hours in order to get straight again. He was familiar with forest trees, and knew just where to go for any timber desired. He could direct men where to find a chestnut, a maple or an oak, and the children where to go for berries. He was a good mathematician, and could compute accurately and rapidly. In olden days he was quite musically inclined, and, like most blind people, he had a genius in that direction.

HOW TO LAUGH.—As to laughing, how seldom, except on the stage, do we hear a really musical laugh! Some girls make dreadful grimaces when they laugh. A little education in the art would not make it artificial, and they would surely enjoy it all the more if they could realize that they might indulge in mirth without making themselves look so very ugly, as is occasionally the case. It runs in families sometimes to distort the countenance in laughter. I know a family who laugh a great deal. Their eyes always shut up when they do so, and it is the funniest thing when one dines with them and something amusing is said, to look round the table and see exactly the same distortion on every face. There is not an eye left in the family. Three sisters whom I know show quite half an inch of pale pink gum when they laugh. In their presence, like Wendell Holmes, one "never dares to be as funny as one can," for fear of seeing this appalling triple vision of gums. A little training in childhood would make their laughter a pleasant thing to look at, for they have all pretty little square teeth, very white and even. Henry Ward Beecher says: "A good laugh is worth a hundred groans in any market," and I am sure a pretty one is worth a thousand. —*London Truth*.

A Remarkable Case of Somnambulism.

Prof. Fischer describes a remarkable case observed by himself and others, when a boy at school. A young man, apparently of a hale constitution, and far from exhibiting any symptoms of a nervous temperament, was habitually subject to somnambulism. His fits came on regularly about 10 o'clock at night. The scene was a large apartment, containing 60 beds in four rows. He ran about violently, romped, wrestled and boxed with his companions, who enjoyed the sport at his expense. "I think," says this Professor, "I can perfectly well remember that, while running, he always held his hands before him, with his fingers stretched out. He was remarkable agile, and would leap over the beds, and his companions could scarcely ever catch him. When he escaped through the door, he flew through a long gallery to his own apartment. There he rested, frequently taking up a book and reading softly, or with a loud voice conducting—if my recollection serves me accurately—his outstretched fingers over the lines. His eyes were alternately open and closed; but even when open they were incapable of vision, being convulsively drawn upward, showing only the whites. The general belief that somnambulists see by means of the points of their fingers, as well as the observation that while running our somnambulist always carried his hands and outstretched fingers before him, as if these were his organs of sight, as also his reading (as it appeared to us) by means of the points of his fingers, led us to the idea of tying gloves upon his hands and stockings upon his legs. Besides, we had been informed that during his nightly wanderings he had been known to play at skittles—a game he was very fond of when awake—and that he had always accurately counted the number of pins knocked down by stretching out his fingers in a direction toward them, so correctly, indeed, that it was impossible to deceive or impose upon him. In short, we seized the opportunity of his most profound sleep and insensibility to tie on the gloves and stockings. At this usual time he rose up and sprang out of bed; but although we began to tease and provoke him, he did not move from the spot, but appeared puzzled and perplexed, and groped and tumbled about like a blind or drunken man. At length he perceived the cause of his distress, and tore off the gloves with great violence. Scarcely were his hands uncovered when he started up in a lively manner, and threw the gloves with ironical indignation upon the ground, making a ludicrous observation upon the means taken to blind him; and then he began to run through the apartment as formerly." —*N. Y. Mail*.

LIABILITY FOR INJURIES TO RAILWAY EMPLOYEES.—In connection with the discussion in England of the Employers' Liability Bill, the advocates of that measure have issued a paper describing the laws in force in France and Germany. It states that in Germany an Imperial law, passed June 7, 1871, and extended in 1872 to Alsace-Lorraine, contains a provision "that if any person is killed or hurt in the working of a railway, the proprietor is liable for the injury inflicted, so far as he cannot prove that such injury was inflicted by a higher power or by the fault of the person so killed or injured." A similar system exists in regard to mines and manufactures, and it is said to be common in portions of Germany for employers to club together to form accident insurance societies for the purpose of insuring the lives of their workmen. In France a general law applicable to employers, which also governs the operations of railway companies, contains a provision that "a person is responsible not only for the injury caused by his own act, but also for that which is caused by the act of persons for whom he is bound to answer, or by things which he has under his care." The French railway companies have established provident institutions for the benefit of their employees; but it is stated that even this precaution has not prevented frequent litigation in cases where men have been injured while engaged in the performance of their accustomed duties. —*Railway World*.

TO MAKE A STRONG PASTE.—To make a paste for fastening bills in a file book, or for any purpose where a very strong paste is desired, the following recipe is recommended: Rice or starch paste is the best. Four parts (by weight) of fine glue are allowed to soften in 15 parts of cold water, and then moderately heated until the solution becomes quite clear; 65 parts of boiling water are now added, with constant stirring. In another vessel 30 parts of starch paste are stirred up with 20 parts of cold water, so that a thin milky fluid is obtained without lumps. Into this the boiling glue solution is gradually stirred, and the whole kept at a boiling temperature for a short time. After cooling a few drops of carbolic acid are added to the paste. This paste is exceedingly adhesive, and may be used for leather as well as for paper and card-board. It should be preserved in corked bottles to prevent evaporation, and in this way will keep good for years.

NEW CANAL IN CHILE.—The *Chilean Times* announces the completion of the Canal de la Merced. The canal is 75 miles long, and has been 25 years in construction. It is considered one of the most important works executed in Chile. It has cost about \$400,000.

SAN FRANCISCO, May 25, 1880.
MESSRS. DEWEY & Co.—GENTLEMEN:—In acknowledging receipt of my two patents, I desire to express my thanks for the prompt attention which my business has received. The successful manner in which you have conducted the same shows a marked ability as Patent Agents, and I shall take pleasure in recommending your firm to all who desire to obtain patents. I have received copies of the MINING AND SCIENTIFIC PRESS containing descriptions of my inventions. With the best of wishes, I remain,
Yours truly,
LOUIS BRON.

John Olsson, Model Maker.

Models for the Patent Office, in Wood or Metal. Separate rooms for inventors to perfect their inventions. Chemical Apparatus. Pressing and Stamping of all kinds of Metals.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.]

FOR THE WEEK ENDING AUGUST 31st, 1880.

231,776.—HOISTING MACHINE BRAKE.—W. E. Eckart and H. C. Behr, S. F.
231,806.—THRUSHING MACHINE.—C. A. Jenkins, Sacramento, Cal.
231,850.—SCRAPER.—A. Rewrick and J. D. Gilmour, S. F.
231,849.—KEY-BOARD.—C. C. Reynolds, Kelseyville, Cal.
231,687.—WATER-CLOSET TANK.—W. Smith, S. F.
231,693.—CONVERTING SCRAP INTO BAR STEEL.—S. Wren, Sacramento, Cal.
231,874.—BOILER.—J. B. Ward, S. F.
9,309.—(reissue) WHEELBARROW.—W. McKibbin, S. F.
NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

SUGAR MOLDING MACHINERY.—William H. Wiester, S. F. Patented August 24, 1880. No. 231,638. In this machine the molds are filled, their contents discharged in molded form onto plates on a belt; delivering them to the drying room. The loose particles of sugar are pushed off, the molds are washed and their sliding bottoms pushed back in place ready to receive their next charge. This operation is rapid and continuous and automatic, requiring no attention or skill on the part of the attendants.

RUDDER.—Uriah B. Scott, Portland, Oregon. Patented August 24, 1880. No. 231,623. This invention relates to certain improvements in that class of rudders known as "balanced" rudders, such as are commonly used on light-draft stern-wheel river steamers; and the improvements consist in providing a curved or bent rudder stock, so that when the rudder is turned it will fit close to the bottom of the boat at all points of its swing, thereby preventing drift-wood or other obstructions getting between the rudder-plates and bottom of the boat.

The Pacific Coast Steamship Co.

One of the most important factors which has aided in developing the southern parts of this State is the Pacific Coast Steamship Co. It is now some 15 years since this company commenced operations on a very small scale, but after a while they ran so strong an opposition to the Pacific Mail Steamship Co., that in 1873 the latter sold out the whole coast line to the new company. At that time the Mail Co. was running two steamers to San Diego, and the Pacific Coast Co. was running but one.

For a good many years previous to this most of the coast trade at the smaller southern ports was carried on by sailing vessels, mostly schooners. At the larger places the Mail Co. stopped, but the schooners did a very thriving trade. This was not very satisfactory to the people, however, as there was no regularity and very often their cargoes were damaged.

When the Pacific Coast Steamship began running all this was changed. Five large, elegant and finely equipped steamers took the place of the schooners. The service became regular and rates of freight and passage were lowered. Considering the distances and amount of traffic, the Steamship Co. consider that the freight is lower on the southern coast of California than on the Eastern seaboard south of New York for same distances, saying nothing of the difference in population and the fact that not one ton of freight is carried here for 20 tons there.

As far as communication is concerned, many of the places on the coast have been made by the Steamship Co. The convenience of shipping has brought the land up to good prices and given an opportunity for the crops to be readily marketed.

The company own a fine fleet of steamers, many of them upwards of 1,500 tons burden. It exercises an important influence on southern California. Many of the landings are expensive to keep up, and altogether the circumstances under which freight is handled causes considerable expense. The steamers of this company also run north to Oregon and all points along the coast, where a very flourishing business is done.

NEW mines have been discovered in El Dorado canyon, San Bernardino. Ore from the Lone Star mine assays \$2,000 per ton, ore from the Savage \$1,720, and ore from the Morning Star \$5,900, with others up in the hundreds.

AN exhibit at Little Rock, Ark., of silver bullion from ores of the Montgomery county silver mines has created much excitement there.

Mechanics' Fair Notes.

Culver's Elevator.

Mr. James H. Culver, the accommodating Secretary of the Mechanics' Institute fair, is also an inventor, and exhibits at the southwest corner of the pavilion, near the stairway, an improved safety device for elevators, which while simple, exhibits considerable ingenuity. The invention consists in constructing at the bottom of the elevator well an open topped hollow box, into which the elevator may fall in case the rope breaks or unwinds, and the ordinary safety clutches do not act.

This box has suitable discharge openings for the air to pass out gradually where the elevator or cage drops into it, and the partially confined air acts as a cushion into which the cage falls, so that its speed is checked gradually, and no harm results to the occupants of the cage. Springs may also be placed in the bottom of the box, which will also tend to lessen the force of a fall. It is well known that cages will frequently fall when the rope does not break but unwinds from the reel. When this occurs the safety clutches seldom act, and the cage is precipitated.

By having this air chamber or box at the bottom of the elevator well should any accident of any kind happen, and the cage be precipitated downward, instead of the cage being broken to pieces and the occupants killed or maimed, it strikes on a cushion of air and is gradually brought to a stand-still.

As the floor of the cage or elevator first strikes into the box the air is compressed, and begins to issue from the discharge opening, the opening gradually being reduced in size as the cage goes lower, while at the same time the air is more and more compressed. This action has the effect of slowing down the motion so gradually that no harm can occur to the cage or its occupants. As the cage nears the bottom it meets the springs, which it compresses, and is then brought to a stop.

By thus falling on to an elastic compressible cushion of air no jar or shock is experienced, as is the case where the elevator strikes on to a floor or timber at the bottom of the well.

There is no mechanism in this safety apparatus to get out of order, and it works very smoothly. A bucket of water is placed on the elevator at the fair and the cage dropped, the water not being spilled, which shows how smoothly the cage is brought to a stand-still. Mr. H. B. Herrick has the elevator on exhibition.

Betts' Springs.

Among the flourishing home industries represented at the Mechanics' fair is that of the manufacture of carriage springs. The Betts Spring Co., the only one here exclusively engaged in this branch of business, make a very handsome display of different varieties of springs, made even more creditable from the fact that many original improvements are incorporated in the work.

All of these springs are made of the best refined English steel, which is imported in long bars, from one and a half to four inches wide, the edges being slightly rounded off, ready to make up. In the process of manufacture, while the leaf is being formed a "lip" is made on the leaf. This "lip" is a very important improvement over the old-fashioned way of making light springs, and is an invention of Mr. Betts. Formerly, in placing one leaf above another, it was necessary, in order to keep them in position, to cut two slots and punch two teats in each leaf, which, of course, weakened the spring. Each of these slots was about half an inch long, and, in making the two in each leaf, the piece of steel was frequently broken, and always weakened. The teat or projection in each side of the center of the leaf fitted into corresponding slots in the leaf below it, thus preventing the leaves from getting out of position. The "lip" invented by Mr. Betts is simpler, and answers the purpose better, without weakening the leaf in the slightest degree. It consists of a slight projection formed on the side of the spring, a short distance from each end. This being formed on each leaf, laps down beside each lower leaf, each one assisting to keep the other in position, and preventing lateral motion. These lips, therefore, do away with the slot and teat, and the springs never give way where the lip is. The machine for forming the "lip" was devised by Mr. Betts.

Most of the machinery for carrying out the different operations in the manufacture of these things has been designed by the proprietors, and is of their own construction. The business has been established on the quality of the work performed, no outside assistance having been rendered, and they have succeeded in introducing these springs almost everywhere on the coast. The works were established here some thirteen years since, with one man and a boy; now they give employment to a large number of hands, and supply all the wagon and carriage-makers in this city with springs, as well as sending quantities of them to the interior and all over the coast. In the display in the fair are shown the different varieties of springs made by the company.

The Glass House.

Probably the most unique of the many noticeable displays in the fair is the artistically arranged collection of cut, stained, bent, embossed and painted glass, which has the appearance, as a whole, of a finely finished glass house. It is elegantly arranged, and attracts considerable attention as the product of a home industry of a peculiarly artistic character.

Among the many fine specimens of embossed glass the representation of the seal of California is perhaps the most prominent. It is handsomely encased in a frame of fine etched architectural work. In fact the architecture is made up of myriads of fine lines and curves, and deserves special mention. The glass is silvered, and answers partly as a mirror. The delicacy and exactness of the whole picture places it in a high order of art.

The variety of figured colored windowes for churches commands attention, as does the glass painting for house decoration. The cut glass department exhibits some unique monograms, door lights and leveled glass. John Mallon, 19 Fremont St., and 1213 and 1215 Howard St., is proprietor of the works from which this glass is turned out, and deserves great credit for the progress shown in his art. He has been in the business here for some 23 years, and has furnished the ornamental and bent glass for nearly every elegant mansion in the State, the latest large job being that in the mansion of J. C. Flood, Esq., at Menlo Park.

Henricksen's Safety Clutch for Elevators.

B. E. Henricksen exhibits in operation at the fair an elevator which is provided with his patent safety clutch, a device intended to catch and sustain the cage in case the hoisting rope breaks or the hoisting apparatus is deranged. Trip levers are pivoted to the frame of the cage and have toothed cams at their lower end. They are inclined outwards, and have at their upper ends rollers which bear against irregularly-formed cleats or horses on the sides of the guide posts. At the ordinary rate of speed these rollers move along on the edge of the cleats, these cleats being formed in wave lines.

Should the cable part, or any portion of the machinery break, the rollers are brought in violent contact with the cleats, which, having a sharp incline on the top part, will throw the trip levers over and bring the clutches or cams in violent contact with the guide posts, so that they engage with them and act as brakes or safety levers, preventing the cage from falling further. The eccentrics or cams are toothed and form a powerful brake, which increases in power in proportion to the strain which is brought upon them.

The operation of this device depends on speed alone. At the ordinary rate of speed the cams are not brought into action. The moment, however, that the speed becomes too great for safety, the trip levers operate and the cage is stopped. This device is in use on elevators in the following buildings: Johnson building, No. 120 Sutter St.; Thurlow block; S. F. Stock Exchange; No. 545 Market St.; W. Cohn, northwest corner of Battery and Bush Sts.; W. & J. Sloan, 545 Market St.; J. Carl & Co., 517 Market St.; Halleck block; California Furniture Company, 226 Bush St., etc.

Domestic Sugar.

The Standard Sugar Manufacturing Co. have on exhibition at the Market St. end of the Pavilion near the stairway, samples of sugar made from beets at their works at Alvarado, Alameda, Co., that will compare favorably with any sugar from the refineries of this city or from the East.

But few people are aware of the enormous quantities of sugar annually imported into this country. The people of the United States send to foreign countries every year nearly \$100,000,000, for sugar that no doubt could, and should be produced at home. If this was done, that large amount would be distributed among our own people, instead of being sent abroad to enrich the subjects of foreign nations.

And no doubt this desirable result would have been attained years ago had our Government pursued as liberal a policy to encourage this important industry as those foreign nations that now, not only produce a sufficient amount of sugar from beets to supply their own wants, but have a large surplus for export.

A strong prejudice has naturally existed in this community against beet sugar. Until this company commenced operations (which was only last year), either from a lack of knowledge or proper machinery, sugar manufacture from beets has not been properly refined. Sugar from cane, refined in the same manner, would have given no better satisfaction. Sugar produced from the beet and cane, are chemically the same and are known in chemistry as cane sugar, only, and are equally pure when properly refined. It is claimed, however, that beet sugar contains less glucose than that made from sugar cane and is really sweeter and more pure, when properly refined.

If a good quality of sugar can be manufactured from raw material produced in our own country in sufficient quantities for home consumption, it should receive every possible encouragement.

WALKING ON WATER.—At Milwaukee, on the 7th inst., a young Norwegian named Rosendahl gave an exhibition of walking on the water, which is described as a complete success. Attached to the young man's feet were two floats, or "boat-like structures," by the aid of which he is said to have walked easily and quite rapidly on the surface of the water. His movements were an actual walking motion; it was not a dragging motion, but a straightforward walk at the apparent rate of three miles an hour. At the time of the experiment a passing tug-boat caused quite a swell on the water without, however, disturbing the action of the walker. The feat was performed in the presence of thousands of spectators.

News in Brief.

A NEW and fatal cattle disease has broken out in Kentucky.

THIS year the American cotton crop is the largest ever raised.

THE port of Fusan, in the Corea, has been opened to Italian commerce.

PETER CAMPBELL, of Bridgeport, challenges the world to a whistling match.

ATTEMPTS are making to circulate \$50 forged American bank notes in London.

THE bones of a mastodon were recently examined in Washington county, Or.

O. F. DAVIS, a telegraph operator, was killed on the railroad near Pantana, Arizona.

DR. HAYES, the Arctic explorer, expresses his belief in the safety of the Jeannette.

THE volume of Kern river is three times greater than at the same time last year.

JOSEPH HANCOCK was suffocated by foul gas in the New Almaden mine on the 31st of August.

WILLIAM H. GREENWOOD, an American railroad engineer, was murdered in Mexico on Aug. 29th.

THE young man of the period allows his mind to run on monkey jackets and polka dotted socks.

NINETY-SEVEN lives were lost by the giving away of the pontoon bridge over the river Ebro, Spain.

A FARMER states that a corn-cob is better than any brush for cleaning woolen clothes from mud and stains.

LONDON placards announce that Spurgeon's figure has been added to Madame Tussaud's wax-works.

MANUEL SILVA, of Pajaro, has threshed a field of wheat which is said to have yielded 103 bushels to the acre.

THE "Queen's Printer" in England has a monopoly of the business of printing and publishing the Bible.

SRUZZON is a noted Indian village on the Fraser river. It is the home of a thrifty and christianized tribe.

GEORGE TUCKER, an inmate of Auhurn prison, has just inherited \$12,000. His sentence will expire in 1885.

JOSEPH COLE, of Central Point, Merced, has lost inside of three weeks over 300 chickens by the sneaking coyote.

CONSIDERABLE attention is being paid to raising silkworms in Amador county, and they are said to thrive well there.

MISS JOSEPHINE TAYLOR, daughter of the head of the Mormon church, has fled from her home to escape polygamy.

ENGLISH Sunday schools have no picnics or festivals, and the children are less regular in attendance than in America.

It is proposed to raise \$25,000 in Petaluma and build a new and fast steamer for use on the creek route to San Francisco.

They say at the London jockey club that Mr. Lorillard's two-years' career on the English turf has cost him nearly \$200,000.

BISHOP ELDER of Cincinnati has declared that no hanged or frizzed hair will be allowed among the women of his congregation.

RESIDENTS of Livermore valley tendered a reception and picnic to the Tulare settlers, who reached that place the other day.

A PARTY of picnickers were poisoned, Sept. 21st, at Geneva lake, Wis., by eating pressed beef. Eight persons are dangerously ill.

NEGOTIATIONS are proceeding with French capitalists to raise funds in Paris for the construction of the St Lawrence tunnel.

CASTROVILLE farmers use horses to trample out their mustard seed. This does away with the employment of Chinese with flails.

SOME pretty fans are to be seen at the watering places, this year, but the loveliest is declared to be of white lace applied on a background.

THE steamer *San Salvador*, plying between New York and Truxillo, Honduras, and engaged in the cattle business, is reported to be lost.

THE Bodie stage was robbed on Sunday, Sept. 5th, and one robber was killed, a messenger was wounded, and the treasure box was taken.

It is reported that Prof. Henry L. Kendrick, of the chair of Chemistry at West Point, is about to be retired by the President under the longevity law.

MISS ALICE HARLOW, of Augusta, a recent Vassar graduate, accepts the professorship of Latin and Greek at Monticello seminary, Godfrey, Ill.

THE American humane association has deposited \$5,000 with Kidder, Peabody & Co., at Boston, to be awarded the inventor of an improved cattle car.

CUSTOMERS on a milk route in New Haven, Conn., are supplied by a woman who in all sorts of weather drives her rounds with unfailing regularity.

GEORGE MEEK, of Windsor, Sonoma Co., who was bitten by a fox, has, after much suffering died from hydrophobia, caused from the animal's saliva.

THE Illinois Central has paid more than \$36,000,000 in dividends in the last 20 years, besides reducing its funded debt to \$10,300,000 on \$45 miles of track.

AN English member of Parliament thinks that the next session promises to be fraught with very important events in connection with the woman's suffrage movement.

THE house still stands in Salem, built about 1632 by Roger Williams, in which is a low room, with solid oak beams and timbers, where the witch's trials were held, and whence many victims were led out to die.

Pocket Mining Atlas,
Containing the principal mining districts in the United States. Compiled from the latest official surveys and the most authentic sources by Edwin Bolithe. Sent, post paid, on receipt of \$1. Address, Dewey & Co., 202 Sansome St., S. F.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omissions of agents.

Various Causes—
Advancing years, care, sickness, disappointment, and hereditary predisposition—all operate to turn the hair gray, and either of them incline it to shed prematurely. **ATZKA'S HAIR VIGOR** will restore faded or gray, light or red hair to a rich brown or deep black, as may be desired. It softens and cleanses the scalp, giving it a healthy action. It removes and cures dandruff and humors. By its use falling hair is checked, and a new growth will be produced in all cases where the follicles are not destroyed or the glands decayed. Its effects are beautifully shown on brashy, weak, or sickly hair, on which a few applications will produce the gloss and freshness of youth. Harmless and sure in its operation, it is incomparable as a dressing, and is especially valued for the soft luster and richness of tone it imparts. It contains neither oil nor dye, and will not soil or color white clothing; yet it lasts long on the hair, and keeps it fresh and vigorous.

FOR SALE BY ALL DEALERS.

How to Stop This Paper.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for \$3 per (half-yearly) volume. In cloth and either binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

INVENTORS, and others interested, will receive DEWEY & Co.'s MINING AND SCIENTIFIC PRESS PATENT AGENCY Circular free on application at this office. It contains 42 pages of hints and information about Patents, Patent Laws, Patent Office Regulations, and how to obtain valid patents.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus, terms of subscription, etc., and request that they circulate the copy sent.

J. G. COLMBENIL is requested to report to this office from Humboldt Co.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

Chew JACKSON'S BEST Sweet Navy Tobacco.

Some fine sunny offices (next to the PRESS office), to rent (at very reasonable rates), by Dewey & Co., at 202 Sansome street, corner of Pine.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

DIVIDEND NOTICE.
OFFICE OF THE
Napa Con. Quicksilver Mining Company,
SAN FRANCISCO, AUGUST 30th, 1880.

At a meeting of the Board of Directors of the above-named Company, held this day, a Dividend (No. 12) of Ten (10) Cents per share, was declared, payable on WEDNESDAY, the first day of September, 1880, at the office of the Company, Room 16, Academy Building, No. 330 Pine St., San Francisco, California.

W. M. W. PARRISH, Secretary.

DIVIDEND NOTICE.
OFFICE OF THE
Standard Consolidated Mining Company,
SAN FRANCISCO, SEPTEMBER 1, 1880.

At a meeting of the Board of Directors of the above-named Company, held this day, Dividend No. 19, of Seventy-Five cents (75) per share was declared, payable on MONDAY, September 13, 1880, at the office in this city, or at the Agency of the Nevada Bank of San Francisco, in New York.
WILLIAM WILLIS, Secretary.
Office—Room No. 29, Nevada Block, No. 309 Montgomery St., San Francisco, Cal

Gover Mining and Milling Company.—
Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.
Notice is hereby given that at a meeting of the Directors held on the Eleventh day of August, 1880, an assessment (No. 4) of 20 cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 402 Front street, room 8, San Francisco, California.
Any stock upon which this assessment shall remain unpaid on the Thirtieth day of September, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Monday, the Eleventh day of October, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale.
W. D. WILSON, Secretary.
Office—402 Front street, room 8, San Francisco, California.

Techattucup Silver and Gold Mining Co.
Location of principal place of business, San Francisco, California. Location of works, El Dorado canyon, Lincoln Co., Nevada.
Notice is hereby given that at a meeting of the Trustees, held on the 24th day of August, A. D. 1880, an assessment (No. 7) of One Dollar per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, No. 237 First street, San Francisco, California.
Any stock upon which this assessment shall remain unpaid on the 30th day of September, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Wednesday, the 20th day of October, A. D. 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale.
O. F. MOULTHROP, Secretary.
Office—No. 237 First street, San Francisco, California.

INGERSOLL Rock Drill and Air Compressor.

The undersigned having been appointed sole agent for the Pacific coast, will keep always on hand a large stock of the various sizes, together with duplicate parts, all of which he will sell at factory prices. The Ingersoll is the only Rock Drill now in use on the Comstock.

GEO. R. FOARD, GEN'L AGENT,
No. 18, First St., S. F.

INCERSOLL ECLIPSE ROCK DRILLS.

The Most Economical Air Compressors in the Market.

MINERS' HORSE-POWER.

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The Power is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending the bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX,
49 Fremont St., S. F.

California Inventors Should consult DEWEY & CO., AMERICAN AND FOREIGN PATENT SOLICITORS, for obtaining Patents and Caveats. Established in 1860. Their long experience as journalists and large practice as patent attorneys enables them to offer Pacific Coast inventors far better service than they can obtain elsewhere. Send for free circulars of information. Office of the MINING AND SCIENTIFIC PRESS and PACIFIC RURAL PRESS, No. 202 Sansome st., San Francisco.

BOESCH'S PATENT
Hydraulic Mining and Locomotive Head Lights, with the Latest Improvements, making them the best and cheapest in the market.
Pacific Lamp and Reflector Factory.
569 Mission St., San Francisco.

**COPP'S

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 129 Lithographic Diagrams. 1867.
This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 129 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50
ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.
This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and the wherefore.
It contains 151 pages, embracing illustrations of furnaces, implements and working apparatus.
It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.
Price, \$3.00 each, postage free.

Engraving. Superior Wood and Metal Engraving, Electrotyping and Stereotyping done at the office of the MINING AND SCIENTIFIC PRESS, San Francisco, at favorable rates.

LAND
Good land that will raise a crop every year. Over 14,000 acres for sale in lots to suit. Climate healthy. No drouths, bad floods, nor malaria. Wood and water convenient. U. S. Title, perfect. Send stamp for illustrated circular, to EDWARD FISKE, Proprietor of Reading Ranch, Anderson, Shasta County, Cal

DEWEY & CO'S Scientific Press Patent Agency.

(ESTABLISHED 1860.)
Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

HYDRAULIC GRAVEL ELEVATORS,

For working flat gravel mines that have no dump.
Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Hauls rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.
No hedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding homastic and pretentious claims by others.

- No. 1 (XX) is the Strongest Explosive Known.
- No. 2 is superior to any powder of that grade

STEIGER & KERR'S CONTINUOUS DISCHARGE AND GRINDING PAN.

This pan is designed to receive ore direct from a rock breaker, and reduce it to the fineness necessary for amalgamation, thus taking the place of the ordinary stamp battery. The cost of this Mill places it within the reach of all; and one point of advantage not to be overlooked is the fact that the cost of erection, which adds so much to the expense of the stamp mill, after it leaves the foundry is, in this case, reduced to a fraction, as the Mill is complete in itself, and requires no expensive foundations, bed logs, battery frames, etc., but can be placed in position in a few hours after it arrives on the ground, without the aid of skilled labor. This simple arrangement, durable as it is simple, is a most important improvement in the working of gold ores, as it enables parties to construct and erect a mill at half the cost of a stamp mill, and with a great saving of time, and size of mill building. Each pan is capable of reducing 10 tons of average ore in 24 hours, the ore being first broken in a rock breaker, small enough to go through a half-inch screen. There is an important point in the action of this Mill, to which we desire to call the attention of miners and millmen. We allude to the grinding and scouring action on the gold before it is discharged. The value of this point cannot be over estimated, and it is not necessary to do more than mention the fact, as it will be at once recognized by all competent millmen who examine the pan in operation, and especially by those who have had to deal with tarnished or rusty gold, as it is commonly called, and which is often encountered in our mines, and which is such a cause of loss. The pan of feeding is the same as in the stamp mill, either an ore feeder or hand feeding being adopted, as may be desired. Parties interested in mining and mills can see the Pan in operation by calling at the OCCIDENTAL FOUNDRY, STEIGER & KERR, 137 First St., S. F.

FROM 1-4 TO 10,000 lbs. WEIGHT.

True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. SECURE PATENTS

Through Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free. DEWEY & CO., PATENT AGENTS.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

A New Hot Air Engine.

When the original Ericson calorific engine came out, greater things were expected of it than were ever realized; and in fact it was rather unsatisfactory. The need of such a motor, especially for small work, has long been recognized, but until lately it has seemed one among the unattainable things. The great trouble has been that the motors have been too large or too expensive, or too complicated.

Mr. Ericson has within a few months patented an improved motor, specially designed for pumping water, an engraving of which we give herewith. We examined the machine this week at H. P. Gregory & Co.'s, the agents, where a small-sized one may be seen at work, a larger size being also on exhibition at the Oakland fair. It is intended for use in places where small quantities of water are to be lifted short distances cheaply.

The engine consists of an upright cylinder, cast in one piece, the lower portion being suspended in the fire-box or furnace, while the upper portion is surrounded by a water-jacket. This cylinder is supported in the center by a simple iron table having four legs, and raised high enough to admit the furnace under the table. The furnace under the cylinder may be a small, cylindrical wood or coal stove, with a suitable chimney, or four gas-jets inclosed by a sheet-iron box, having an opening at the top for the escape of the products of combustion. The use of gas is to be preferred to coal or wood wherever it can be obtained, as it is cleaner, cheaper, and much less liable to injure the machine by overheating. That we examined at Gregory & Co.'s is run by gas. The moving parts consist of two pistons, placed one over the other in the cylinder, and their proper connections by means of a walking-beam and bell-crank. The theory of the engine is this: The lower piston, or plunger, is quite long, filling about one-third of the cylinder, and not quite touching the sides and bottom. Stud on the sides of the plunger serve to guide it in the cylinder. The upper piston fits the cylinder air-tight, or very nearly so, and moves up and down in the cylinder over a portion of the part that is water-jacketed, the upper side of the piston being exposed to the air. The rod for the plunger passes through the center of the piston-rod, and both plunger and piston move independently of each other.

On starting the fire under the cylinder the air inside becomes heated, and by giving the fly-wheel a slight push the motor starts into operation. The plunger descends quickly, driving the heated air at the lower end of the cylinder past the sides of the plunger to the upper part of the cylinder, where it meets the piston and forces it upward, and giving the first stroke to the engine. At the same time, the hot air meets the cold sides of the jacketed portion of the cylinder and contracts, makes a partial vacuum under the piston and escapes back to the lower portion of the cylinder, where it is again heated. The fly-wheel carries the plunger down again with a quick stroke that compresses the heated air, and it again expands suddenly and reacts upon the piston above, when the action is repeated. The same air is used continuously, being alternately heated and cooled, expanded and contracted; the conversion from one condition to the other developing the power required to keep the machine in motion, and enable it to do useful work. The system of cranks for controlling the movements of plunger and piston is simple, and in operation the motor works in silence. The pump is placed at the side of the cylinder, and is connected directly with the walking-beam moved by the piston. It takes the water through a suction-pipe, and passes it through the water-jacket and thence on to the discharge, the slight absorption of heat in passing through the jacket being of no particular consequence, while the fact that none of the

water passes the jacket twice insures a constant supply of cold water in cooling the cylinder. The motor is made in two sizes, the larger size with a cylinder 20 m. (8 in.) in diameter, and consuming 420 cubic decim. (15 ft.) of gas per hour, having a duty of 1,400 liters (350 gals.), raised 15.07 m. (50. ft.) an hour. It cannot explode, nor is there danger of fire, and any intelligent person may learn to use it with safety in half an hour.

SPECIMEN FROM ROCKY BAR.—The Grass Valley Union of the 14th inst. says that among the

INVENTOR OF THE TELEPHONE.—Prof. Alex. Graham Bell has received the Volta prize of the French Academy of \$10,000 for the invention of the telephone, as "the best application of electricity." Prof. Bell is also the inventor of the photophone, which he is said to regard at present as a scientific toy, as the telephone was regarded at first. The future use of the photophone will be, he thinks, between ships at sea, wrecks and the shore, and for military communication. Prof. Bell announced the possibility of producing sound by interrupting the action

A Premium for Improvements.

It must be confessed that, as a general thing, the improvements introduced in manufacturing establishments by the hands, are more apt to redound to the benefit of the "hosses" than to the individual "hand." By this we do not mean patented inventions, but such devices as simplify or expedite work, or such a modification of tools as admit their being put to more than one use, etc. While the fact that such things

are done in a shop in large manufacturing establishments is noticed by the proprietors, and the individual doing them is recognized as perhaps above the common run, it is not always that any substantial recognition of his services is made.

It is pleasant to note that an English ship-building firm (Messrs. Wm. Denny & Bros., of the Leven Yard, Dumbarton), have set an example, which, if more frequently followed, will be to the benefit of both employer and employee, and will make a change in the existing customs. This firm has issued an intimation to their workmen, in which they state that having noticed during the past two years many improvements in the methods of work and appliances introduced by their workmen into their yard, they readily recognize the advantage accruing to their business from these efforts of skill, and are desirous that they should not pass unrewarded. Messrs. Denny have, therefore, decided that the authors of improvements introduced after this date shall have a claim upon the firm for reward; and to enable those claims to be readily and easily adjusted, they have appointed a committee of awards. The rewards are to be given to anyone who has either invented or introduced a new machine or hand-tool into the yard; to anyone who applies existing machinery or hand-tools to a new class of work; to anyone who has discovered or introduced any new method of carrying on or arranging work; or generally to anyone who has made any change by which the work of the yard is rendered either superior in quality or more economical in cost. The awards are not to be less than £2, and not more than £10, but the firm may grant a larger sum if satisfied that the invention is of sufficient importance to warrant them to do so.

It is sincerely to be hoped that this example will be followed everywhere. There is no expense entailed upon the proprietors unless they get an adequate benefit. The workmen receive no extra pay unless they deserve it. It will arouse a spirit of emulation among the men, which can only be full of good to themselves and their employers. We have heard of no better move for a long time. Indeed, we know of nothing at all comparable to it for improving the artisan and rendering his services of higher value to his employer. Besides enlarging the knowledge of the workmen, the research and study and thought will prove a wholesome and valuable discipline. It is a splendid example, and as we have already said, we hope it will be generally followed.

A CENSUS OF THE INDIANS.—A Washington dispatch of Sept. 15th says the work of taking the census of the Indian population of the United States will commence on the 1st of October. It has been placed under the direction of Major J. W. Powell, who will be assisted by Col. Mallory, R. L. Packard, H. W. Henshaw, H. D. Hinman and Clay Macauley. The country has been subdivided into four divisions, and a special agent to superintend the work has been assigned to each division. The work of enumeration will be slow, and it is estimated that at least six months will be required for its completion.

THERE were 180 horses in the Seaham mine at the time of the explosion.

ERICKSON'S NEW CALORIC PUMPING ENGINE

pieces of rich quartz taken out of the Rocky Bar mine the other day, there was one that not only had gold running through it, but one side looked as if it had been gold-plated. The surface was covered with a film of bright gold, the result, undoubtedly, of immense pressure. The fine specimen weighed 117½ ounces troy, contains 49 ounces of gold, and is valued \$830. The Union says this is the richest piece yet produced from the late find in the Rocky Bar.

MECHANICS' FAIR PREMIUMS.—We expected to have the pleasure of announcing this week the award of premiums for exhibits at the Mechanics' fair, which closed on Saturday evening of last week. The committees have duly reported, but the reports have yet to be combined and the result submitted to the managers of the Institute for their approval. For this reason we are unable to announce the awards in this issue of the PRESS.

of light on selenium to the Royal Institute of Great Britain in May, 1878; and shortly afterwards he heard Willoughby Smith announce to the Society of Telegraphic Engineers that he had heard the action of a ray of light on a crystal of selenium by a telephone in connection with it. Prof. Bell was born in Scotland, and was educated at the University of Edinburgh. He arrived in Canada in 1870, and was called to a chair in Boston University in 1872. He is said to be a man of remarkably fine presence.

THE Tioga mining district is in Mariposa county, on the head waters of the Tuolumne river, near the line dividing Mariposa and Mono counties, and about 30 miles easterly of Yosemite valley. It contains many promising silver mines.

STANLEY has stated to a Portuguese captain that the object of his expedition up the Congo is to open a path for traders.

CORRESPONDENCE.

Wadmit, unendorsed, opinions of correspondents.—Eds

Mines of Owyhee County, Idaho.

[Special Correspondence of the MINING AND SCIENTIFIC PRESS.]

EDITORS PRESS:—This district has not been so dull for a long time, but several new and important developments, together with a renewal of confidence on the part of outside capitalists, especially in the New England States, leads us to look for better things in the immediate future. The situation is such that a general review will not be out of place at the present time.

Readers of the PRESS have been kept informed of the march of events here, and are doubtless familiar with the

History of this Camp;

Its discovery in 1863; the intense excitement and rush in consequence of the wonderful finds then made; the organization of local quartz mining companies; the extraction of enormous profits in brief periods; the richness of the surface ores, both of gold and silver; the sale of the leading mines, and, as the usual corollary, of a host of mere prospects to San Francisco capitalists; the listing on the San Francisco Stock Exchange of the stock of these properties, good, indifferent and wild-cat alike, at enormous capitalization; the subsequent fever of speculation in Owyhee mining stocks, fed by the sparse but carefully-planned dividends at the beginning of their career; the erection of extravagantly top-heavy hoisting works on a great number of claims; the

Mismanagement

And defalcation of the principal manipulator in 1875; the mending and heavy assessments paid by a long-suffering public; and the final collapse of the whole stock-gambling edifice. This sums up our history from the discovery of the mines through the flush period and epoch of decline. Since then, Owyhee is considered to have been recovering but slowly from the black-eye thus inflicted, but there are now symptoms of a favorable change in public sentiment, to which, I fear, San Francisco people may be an exception, having in view their past unlucky experience and dreading to again approach the fire which has once singed them (cinched, I believe, would be the more appropriate phrase). However, Eastern capitalists, not having this disagreeable impression ever on their minds, have invested largely here, and will not suffer. The last four years have been an era of

Enforced Economy.

What work has been done has been more carefully supervised, more economical in character and more profitable in results. This change is a healthful sign for the future, but I must say is little relished by many of the old residents, who look back longingly to the flush times when money circulated so freely and carelessly in the camp and fortunes could be made in a few months; but, alas, were never kept. Apart from early extravagance, our people suffered, too, in the general downfall, having had enduring faith in the times, but being innocent as lambs of the intricacies of stock speculation. The result was that nearly all suffered heavily, and on the suspension of the Bank of California not a few here followed suit in sympathy. We have few rich men here now, but many who think they are well on the way toward a fortune, and certainly a considerable proportion who will profit largely by their present mining interests.

Silver City.

The county seat, and the center of the mining industry, was once a flourishing town of from 3,500 to 4,000 inhabitants. It has fallen off to only 800 at present. The neighboring camp of Fairview in 1870 boasted 2,500 inhabitants. Probably 100 would include all that hurg could, with any decency, lay claim to now.

The altitude of Silver City is 6,500 ft. above sea level, and that of the overlooking War Eagle and Florida mountains is 8,000 ft. Silver City has a mild and pleasant climate in summer, but in the winter months the snows are heavy, interrupting communication, and the winds are sometimes high. As might be expected at this altitude, the mercury sometimes gets tired and settles down into its more comfortable bunk in the bulb; but you cannot expect everything in one mining camp. Nature has put the mines in the high places, perhaps so as not to interfere with the agricultural interests; and consequently miners have to live well up in the skies. Silver City is on the stage road between Boise City, Ada county, the capital of the Territory, and Winnemucca, Nev., on the Central Pacific railroad. It is distant 60 miles from the former, and 210 miles from the latter. Teamsters and freight companies used to make a good thing out of hauling from the railroad, from which all our supplies are derived; but they get now only three to five cents per lb., which is quite a reduction, and only haul in the summer months. The time occupied in hauling ranges from two to three weeks.

There are five

Principal Districts

In this county—War Eagle Mountain (or Fairview), Florida Mountain, Wagontown, South Mountain and Flint. On War Eagle Mountain

the principal mines are the Golden Chariot (including the old Minnesota), the Mahogany, Ida Ellmore, South Chariot, Oro Fino, Poorman, War Eagle, Empire, North Empire, South Empire, Illinois Central, Glenbrook, Owyhee, Idlewild, Silver Cord, Red Jacket, Whisky Gulch and Ruth. Of these the Poorman was the most productive, turning out about \$3,000,000 (most of it before being given to the dear public in the shape of stock certificates); the Oro Fino, credited with nearly \$2,000,000; and the Golden Chariot, which produced about the same amount. Many of the other mines have produced over \$100,000. Would that they were doing so now! Nearly all of the mines on

War Eagle Mountain

Have expensive steam hoisting works; the three last mentioned being splendidly equipped, while the War Eagle, Illinois Central, South Chariot, Empire, Owyhee and others are not far behind. The general depth of these mines is from 800 ft. to 1,050 ft. Their best ore was found in the upper levels, but at the time of closing down much good ore was still in sight at the bottom. They are wet mines, and many of them which have not been recently worked are full of water nearly up to their shaft mouth. The War Eagle and Empire have raised a great deal this season in prosecuting explorations below.

The country rock of War Eagle Mountain is granite, forming both walls. The ledges are well defined. They are narrow, but this has been more than compensated for by the richness of the ore. The latter is found generally in pay chutes or chimneys, and in especially rich pockets. Little of the ledge filling has been absolutely barren, it being simply a question of milling and other expenses, as to what would pay for extraction. In some of the mines there is on one wall or both a regular clay gongee.

The Ore

Is a free milling and easily crushed quartz, carrying silver sulphurets, and, especially near the surface, a large proportion of gold. In fact many of the mines could rather be called gold mines than silver ones, if we are to judge by the relative preponderance of the two precious metals. Of this latter character was the Morning Star in its palmy days. I have seen recently many beautiful specimens of surface ores and float in which the gold runs up in the thousands per ton. The cayoite miners and chloriders (you see we have borrowed the old White Pine expression) make a good thing by scratching around on old dumps and in the drifts and stopes of abandoned mines, picking out the rich rock and sorting and sacking it. Several small lots this season were pounded out in band mortars or treated in arastras which produced at the rate of \$1,000 to \$2,000 per ton.

The Crash.

Most of the mines sold under the Sheriff's hammer after the crash, and their works were bought in at absurdly small prices. You could buy a magnificent rig then for \$2,500, which might have cost over \$100,000. The Golden Chariot was one of the few incorporations which managed to hold its property. Stock in most of the others is valuable only as a curiosity now, the mines belonging to others than the companies. I don't know whether all San Francisco holders are aware of this, or are still cherishing their certificates in the hope of another boom in the market; but if they will come up here they will see cords of stock plastered up on the walls of sarcastic former owners, and a good deal in the specimen cabinets for which the town is famous. The Owyhee and War Eagle are being operated by a

Boston Company

Of which Supt. Parks is the representative here. The latter mine turned out over \$100,000 last year. Messrs. Crutcher, Thomas and others are working the old Empire, with good prospects. Martin & Simundi made a good thing, it is said, out of Glenbrook this year. Many of the smaller mines have yielded well. It is a pity that the Golden Chariot, Poorman, Oro Fino and others could not be started up. The cost of running the expensive machinery is a bar to the present owners. Only a company willing to put in some capital could succeed, and for such there are a dozen fine openings at existing prices.

Florida Mountain.

The mines of Florida mountain, opposite War Eagle, on the other side of Jordan (creek), are of comparatively recent discovery, and have been worked only for three years. Last year Gen. John B. Winters, formerly superintendent of the Yellow Jacket, on the Comstock, took out of Black Jack some \$80,000 or \$100,000. The Florida Hill, Sands, Owyhee Treasury, and others, have also made a record. The formation of Florida mountain is altogether different from that of War Eagle mountain, being porphyry throughout. The ore, however, is similar—a free milling silver ore carrying a considerable proportion of gold. The veins here are also plainly marked, and it is a simple matter to follow them. The mines on Florida mountain are worked by tunnels, which the steepness of the mountain side makes possible, and none of them are yet down to any great depth. Miners here have a great idea of the permanence of depth of quartz ledges which are in a porphyry country rock, and would like to see these Florida mountain mines opened at, say, 1,000 ft. or so. For that depth shafts would be necessary.

Wagontown District

Is also comparatively new, but promises well. The country rock here is porphyry, also, and the veins, some of which are big ones, carry a variety of ores. Messrs. Jones & Adams have

applied for a patent on their Wehfoot mines. The old Henrietta has been consolidated with adjoining claims, and is now being worked by the Tremont mining company, of Boston, Mass., with Mr. Tregloan as superintendent. This company is building a 10-stamp dry crushing and roasting mill on Jordan creek, about a mile from the mine. Frank Hunt had a crushing of 100 tons this summer at the Lincoln mill, Silver City, from the Last Chance. Other notable mines in this district are the Stoddard, owned by T. Regan, the Crown Prince and Bismarck ledges, owned by Wm. F. Sommercamp, the Ohio, Zulu, Monarch, Maggie, etc. Wagontown is 10 miles south of Silver City, and the town itself is about a couple of miles from the mines. The stage road runs through it.

South Mountain and Flint

Districts went to pieces during the general smash, but considerable attention is being paid them now. South Mountain is 25 miles south of Silver City, and Flint is distant 12 miles. The ores of both are base, requiring smelting or leaching. The South Mountain Con. mining company, which once figured on the San Francisco stock list, had a large number of mines, and had just started in to work them, with good prospects, when it too was forced to suspend operations. There are a number of

Quartz Mills

And arastras about Silver City, among which may be mentioned the Golden Chariot, Lincoln, Cosmos, Leonard, South Chariot, Trask's and Wagner's. At Wagontown Messrs. Jones & Adams have a 10-stamp mill. Most of these mills are extensively built and have a fine equipment; the Golden Chariot, which has been idle for a long time, especially. Mr. McGregor has been running the Lincoln 20-stamp mill this summer on ore from the Glenbrook, Black Jack, Ruth, Last Chance and other mines. The mill does good work.

Within a few days some rich rock has been struck in the Whisky Gulch, Addie Leonard and adjoining claims north of Silver City. The only other important piece of news for this letter is the erection of a new mill at South Mountain by Tracy & Jones. They have concentrated on the way from San Francisco. With this start South Mountain is looking up once more.

PAUL WARD.

Silver City, Idaho, August 26, 1880.

A Rich Auriferous Belt.

The strike of remarkable rich gold-bearing quartz in the Rocky Bar mine, last week, serves to verify a fact well known to all the old miners of the district of the extent and value of the system of ledges extending along the west bank of Wolf creek, from Gold Hill to the Allison Ranch, a distance embracing about two and a half miles. From time to time, since the discovery of gold-bearing quartz on Gold Hill in 1850, this belt has produced an enormous amount of gold—an amount that can be counted by millions—a handsome percentage of which was found in just such rich stratifications of which the Rocky Bar now gives an example. All the early miners will recollect the rich specimens, frequently more than half gold, which came from Gold Hill, or the remarkably rich quartz which came from Massachusetts Hill, the old Rocky Bar, New York Hill, the French Lead and Allison Ranch, that made them famous in their day of active working. These mines are all on the same system of veins, that lie close together, and in some instances are on the same vein and are adjoining locations. The Gold Hill was the first quartz location ever made in California, so far as is known to history, and was made in October, 1850. The finding of gold in the quartz created a great excitement among the placer miners, but it was not until the following year that a crude mill was erected for reducing the quartz and extracting the gold. Work was continued upon this location with more or less activity until 1865, during which time it was estimated that not less than \$1,000,000 was produced. The Massachusetts Hill claim was located a short time subsequent to the Gold Hill, but its great riches were not struck until several years later—about 1856. During the life of the mine, which lasted about eight years, over \$8,600,000 was extracted. Work was then suspended because the mine was worked to its limits, it being a square claim, as were all the early quartz locations. In the vicinity of Massachusetts Hill were the old Rocky Bar, Seaden Flat, Ford and Reilly, Stockbridge, and other locations, all of which have produced considerable bullion. None of these claims have been worked to any great depth; they are all held on the square location system; and a consolidation is necessary to their successful working.

South of Massachusetts Hill is the Black Lead, which has produced very rich quartz. The New York Hill is an early-day location, and up to 1865 had produced not less than half a million in gold. From that date it was permitted to lie idle for several years; but for the last five years it has been worked continuously, and is now paying dividends. The best quartz has been obtained from the 800 down to the 1000 level, and the opening of the 1100 level is giving equally good promise. This mine is now worked to a greater depth than has ever been reached by any of the mines along the range mentioned, and the results obtained are strong evidence of the utility of deep working. The new Rocky Bar, now turning out rock of extraordinary

richness, adjoins the New York Hill on the north, and the Ford & McDonald, noted for its constant richness, adjoins the Rocky Bar on the west. To the south of the New York Hill are the Wisconsin, Hartery, Homeward Bound, Lone Jack, Omaha, and several other locations, which have been worked more or less, all of which have been bullion producers, but none have been worked to great depth.

Southwest of the New York Hill is the French lead, which was worked for many years and produced millions, and still has a large body of unworked ground. Farther to the south, immediately on the west bank of Wolf creek, is the Allison Ranch mine. The ledge was discovered in 1854, and systematic work was commenced in the following year. A great deal of fabulously rich ore was abstracted, one crushing of 62 tons alone yielding \$23,000. This mine was worked until 1866, when the rich pay chute seemed to be worked out, although the vertical depth was only 340 ft. Up to that time the books of the company showed that the mine had produced over \$2,300,000. In the same vicinity were other claims that produced bullion to some extent, but we have not the data upon which to estimate their yield.

The above mention suffices to show that this quartz belt, extending from Gold Hill to Allison Ranch, a distance of two and a half miles, by about one-half mile in width, has been the most productive of any quartz region in the State, and for its extent probably the most productive district in the world. These limits do not comprise the extent of this auriferous belt, which can be found both further north and south, but embraces that portion which has proved rich in bullion production, and all lying on the west of Wolf creek, and has no reference to the Oshorn Hill range to the east, which has been prolific in gold, or the Eureka and Idaho vein, which is separate and distinct from the system of which we have been speaking. Many of the claims within the district referred to are idle, and have been so for years, and yet there is scarcely one of them whose real treasures have been developed, because none of the claims located on the dips and angles have been worked to more than superficial depth—the vertical depth of the deepest shaft on any of them not exceeding 400 ft.

It is not claiming too much for the Grass Valley district to say that, notwithstanding mineral discoveries elsewhere, it has proven one of the best and most reliable regions for mining ever discovered, paying better for the money invested than any other, and that it is yet in the very infancy of its gold production. Grass Valley Union.

Boiler Explosions by Mysterious Agencies.

The belief which for many years has been prevalent, that mysterious agencies within a boiler were often the causes of the most disastrous explosions, baffling coroners' inquests, generally resulting in a verdict so mysterious that nobody could understand it, or in throwing the blame entirely on Providence, is fast giving away before the light which is brought to bear by the investigations of practical men. Investigators, who have examined all kinds of boilers under the varying conditions of use, and who have made the subject of boiler explosions a careful study, are explaining the causes of these terrific accidents, and showing how they can be avoided. The causes of boiler explosions are now summed up under four heads, viz., bad material; faulty in type; bad work in construction and inefficiency and carelessness in management. Explosions may occur from any one of these causes, even if in other respects the boiler is sound. So the problem is reduced to its simplest form, and any purchaser or user of a steam boiler can understand what is required. The maker of poor iron would seek refuge under the mysterious agency theory, and so would the mechanical engineer who planned a boiler of faulty type, and the boiler maker whose work was unfit to withstand the load imposed upon it, would find abundant cause for congratulation in the mysterious agency theory. The engineer who must stand before his boiler day after day, year in and year out, would find very little satisfaction in contemplating, that no matter how vigilant he may be, there were agencies in his boiler, that without a moment's warning, may blow him out of existence. The only way to prevent these accidents or diminish their frequency, is to put the responsibility where it belongs. First, upon the manufacturer of the iron; then upon the boiler designer and maker, and lastly upon the boiler owner and user, and the engineer whom he employs. There is no place for cheap, ignorant and careless help here. Nor is there any excuse for the penurious manufacturer, who disregards the advice of his engineer in regard to repairs, until from sheer weakness and inability to hold out longer, the boiler "lets go" and brings consequent destruction and woe. Mr. Robert Wilson in his "Treatise on Steam Boilers," says: "The practice of ascribing steam boiler explosions to obscure causes has been productive of much mischief, as it engenders a carelessness on the part of owners and attendants, who have been led to believe that no amount of care will avail against the mysterious agents at work within the boiler."—The Locomotive.

THE Candelaria mill and mining company filed articles of incorporation. Capital stock, \$10,000,000. Directors—Geo. S. Montgomery, John L. Creighton, Herbert Fountain, Dennie Cullinan and Michael Driscoll.

MECHANICAL PROGRESS.

High-Speed Machinery.

This is a fast age in which we live, but we do not always realize that speed is power. In fact not only power but fortunes. Most of the modern improvements possible to manufacturers are only those which serve to produce manufactured goods in a smaller space of time than before and consequently at a less cost. It is remarkable how little the value attaching to high speeds is watched by manufacturers. We would be prepared to undertake to prove that not more than 10% or 20% of the ordinary machines in an engineer's works are running at their proper speed for maximum production, and if engineers are thus negligent, what must the ordinary manufacturer be? Referring to this point of the proper speed for engineers' tools, it may be borne in mind that the speed of a cutting machine should be regulated by the number of feet per minute traveled over by the cutting face and the quality of the material cut. From 15 to 13 ft. per minute may be allowed for wrought or cast iron, and twice that speed for gun-metal, whilst for steel the speed must be reduced in proportion to its hardness. As a rule, these speeds are seldom approximated to, and it thus becomes a matter of serious loss to the engineering manufacturer that a certain cost of plant is not producing its full equivalent of work in a given time. In the same way, with reference to the prime movers or engines, their development of power is exactly proportionate to their speed; indicated horse power being the product of the gross pressure multiplied into the number of feet per minute, through which the resistance is overcome. Thus a manufacturer who requires increased driving power, may obtain it from his present engine by increasing the speed of the engine proportionately, provided he has sufficient boiler power. About 300 ft. piston-speed per minute is the average speed for which most commercial engines are designed. But they do not all run up to this speed, and it may easily be greatly exceeded if proper precautions are taken.

The two great difficulties to be met in an indefinite increase of speed in prime movers are, first, the shocks produced by rapid reciprocation, and the centrifugal force developed by any weight revolving rapidly round a center. The shocks may be so great as to cause vibrations sufficiently violent to break the frames of bearings, or to shake the motor or machine to pieces. The whole art of preventing these shocks of reciprocation is to receive the reciprocating parts on elastic gaseous cushions of air or steam, so as gradually to destroy the velocity of the reciprocating part before reversal. In high-speed engines this may be well effected by what is termed "cushioning" the exhaust steam. The exhaust part of the slide valve may be provided with such an amount of inside lap as will serve to close the exhaust port some time before the stroke is completed. The imprisoned exhaust steam serves not only to make an excellent elastic cushion to destroy the motion of the reciprocating parts, but also serves to fill the ports and clearance spaces, and thus to promote economical working. The highest speeds of reciprocation may be thus obtained with easy and noiseless working if the amount of cushioning be proportionately increased. Next, with regard to the centrifugal force developed by all material in rapid rotation around a fixed center; this may amount to a great deal—more than is generally anticipated. The centrifugal force so developed has frequently been sufficient to cause the destruction of fly-wheels, centrifugal machines, emery stones, and other high-speeded

machines. The formula $\frac{Wv^2}{2g}$,—in which W is

the weight of any revolving body, v is velocity in ft. per second, and g is gravity—shows that in a fly-wheel six ft. in diameter, and revolving at 1,000 revolutions per minute, each lb. weight, of about four cubic inches on the rim, exerts a radial centrifugal force outwards of nearly 40 tons—that is, more than sufficient to destroy the natural cohesion of cast iron. No massiveness or strength of material will in such cases add to the safety. When the centrifugal force exceeds the tensile strength per square inch, the material must fly to pieces, however massively it is made. But for these dangers and difficulties, the advantage of high speeds for economy in engines and factory plant cannot be too highly recommended. Friction does not increase with velocity. Rather otherwise; the proportion of frictional resistance is considered less for high velocities than for low. The proportion of power obtained from a given weight of material also increases directly with the velocity—that is to say, an engine of the ordinary trade 10-horse power becomes a 20-horse power engine by running at double the usual speed. All shafting may be decreased in diameter inversely as the cube-root of the number of revolutions increase; that is to say, a three-inch shaft may be reduced to 2.4 inches if the speed of revolution be doubled. In the same way the size of driving pulleys may be diminished, as the strain transmitted for a given power decreases exactly with the increase of speed, and the size or breadth of the belt may be also reduced in similar proportion. The whole cost of plant throughout a factory—engine, shafting, plunger blocks, pulleys and belt—may be all reduced in certain proportions to the higher proportion of speeds that may be used. This

in itself should make the practicability of speeds higher than those generally used a subject of careful consideration to all proprietors and engineers of factories or works, besides the certainty of a much greater proportion of work being turned out in a given time than could be the case with lower speeds on the machines.—*Iron.*

IRON IN ARCHITECTURE.—A paper on "Iron as a Material for Architectural Construction," has been read by Mr. James Allanson Picton, F. S. A., before the Institute of British Architects. The object of the paper was to trace out the use, progress and capabilities of iron as building material, and to inquire what influence these capabilities were likely to exercise on construction and design in the future. The author commented on the little mention made of its use for architectural purposes, and pointed out that it was likely to be used to a greater extent in the future in architectural construction and design. The author could not agree with Mr. Ruskin, that iron should be simply used for connecting stones together. The ultimate principle of all true architecture was to use materials within our reach in such a manner as would bring out their capabilities efficiently. The paper concluded by showing how, in a variety of ways, iron could be used, not only for the merely constructive portions of buildings, but for dome lights, galleries, entrance doorways, window balconies, etc. The engineer hitherto had enjoyed almost a monopoly of iron, but the architect, too, might put in his claim, as the material is plastic, and ready to take any form that genius and taste might suggest.

A SHOWER OF RAILROAD SPIKES.—The great demand for railroad spikes has called into existence a remarkable machine, now in successful operation at Pittsburgh. It is the invention of the late Mr. James Swett, and comprises a series of "continuous" rolls handling the material automatically. The iron, in the form of billets two and a half inches in diameter and three and a half ft. long, is taken in by the machine, and in 13 seconds reduced in diameter and increased in length to a rod 36 ft. long, and nine-sixteenths of an inch square. In 40 seconds more this rod is cut in two and is passed through two spike machines, from which finished spikes shower at the rate of 40 tons every ten working hours. By working "double time" five of these machines have turned out 1,100 kegs of railroad spikes per day, each keg containing 150 pounds, or 13 kegs to the ton. The product of ordinary rolls and machines is from two to two and a half tons of finished spikes per working day of ten hours.

AN INGENIOUS CUT-OFF ATTACHMENT has been devised for the steam cylinder of direct-acting engines—such as are principally employed for driving steam pumps, hammers, rock drills and similar machines—by the adoption of which the action is rendered much smoother. In this arrangement, the steam may be cut off at any point. In order to prevent the pressure of steam within the cylinder from being reduced too much below that of the steam chest—which might sometimes happen from too great expansion—small tension valves are employed; these are secured to the main valve opening into the ports, provided with springs, so that, when the difference in pressure exceeds a certain amount, the springs will yield, and allow steam from the chest to yield and enter the cylinder. By means of this cut-off, a softness is given to the stroke, making it without any noise or jerk whatsoever, and with the additional advantage of a considerable economy in steam.—*American Ship.*

HOLLOW GROUND RAZORS.—It is not long since it was confidently asserted that, even if the required quality of steel could be produced here, the United States could never compete with England in the manufacture of razors and other fine cutlery, owing to the excessive cost of grinding and finishing. Like a good many other "insuperable" obstacles to American success in the arts, this seems to have been pretty well overcome, since large quantities of Sheffield razor "blanks" are now sent here expressly to be finished. It seems that the art of "hollow grinding," German style, requires a degree of skill a little beyond that of the Sheffield workmen. Accordingly Sheffield manufacturers have to pay double freight across the Atlantic to secure the fine finish to their razors that the trade now demands.—*Scientific American.*

A DIFFICULT PIECE OF CASTING.—The Ames Co., Chicopee, Mass., have recently finished the most difficult piece of iron casting they have ever attempted. This is an iron tub for a rag engine, and was ordered by the Seymour Paper Co. of Windsor Locks, Conn. The job took eight and a half tons of metal, and the work preparing the mold occupied three weeks. The difficulty of the work consisted in the tub being so large and the sides and bottom so thin. Iron tubs for paper mills have been made before, but they have been cast in sections. They will be much better if they can be made in one piece, and when once in place will last as long as the mill does.

HARDENING GLUE.—The only thing that will render glue perfectly insoluble is bichromate of potash. If you add a little of this in solution to the glue, and after applying the glue to the article expose it to the sunlight, it will become insoluble even in hot water. Better expose for a good while, say an hour or so, to make sure that all the glue has become insoluble.—*Boston Journal of Commerce.*

SCIENTIFIC PROGRESS.

The Cause of Perpetual Snow.

Dr. James Croll, in the current number of the *American Journal of Science and Arts*, says the reason why snow at great elevations does not melt, but remains permanent, is owing to the fact that the heat received from the sun is thrown off into stellar space so rapidly by radiation and reflection that the sun fails to raise the temperature of the snow to the melting point; the snow evaporates, but it does not melt. The summits of the Himalayas, for example, must receive more than 10 times the amount of heat necessary to melt all the snow that falls on them, yet in spite of this the snow is not melted. Notwithstanding the strength of the sun and the dryness of the air at these altitudes, evaporation is insufficient to melt the snow. At low elevations, where the snowfall is probably greater, and the amount of heat received even less, the snow melts and disappears. This, Dr. Croll believes, must be attributed to the influence of aqueous vapor. At high elevations the air is dry and allows the heat radiated from the snow to pass into space, but at low elevations a very considerable amount of the heat radiated from the snow is absorbed by the aqueous vapor in the atmosphere. A considerable portion of the heat thus absorbed is radiated back on the snow, and, being of the same quality as that which the snow itself radiates, is for that reason absorbed by the latter. The consequence is that the heat thus absorbed accumulates in the snow till this is melted. Were the amount of aqueous vapor possessed by the atmosphere sufficiently diminished, perpetual snow would cover our globe down to the sea shore. In a like manner the dryness of the air will, in a great measure, account for the present accumulation of snow and ice on Greenland and on the Antarctic continent. These regions are completely covered with snow and ice, not because the quantity of snow falling on them is great, but because the quantity melted is small. And the reason why the snow does not melt is not because the amount of heat received during the year is not equal to the work of melting the ice, but mainly because of the dryness of the air, the snow is prevented from rising to the melting point. In places like Fuego and south Georgia, where the snowfall is considerable, perennial snow and ice are produced by diametrically opposite means, namely, by the sun's heat being cut off by clouds and dense fogs. In the first place, the upper surfaces of the clouds act as reflectors, throwing back the sun's rays into stellar space, and in the second place, of the heat which the clouds and fogs absorb, more than one-half is not radiated downward on the snow, but upward into space. And the comparatively small portion of heat which manages to reach the ground and be available in melting the snow is insufficient to clear off the winter's accumulation.

DISEASE ORGANISMS.—The organisms described by Pasteur as the origin of epidemics and contagious disease are so minute and few compared with the multiplying swarms of bacteria, etc., pervading all generating solutions, that it becomes necessary to provide a means of eliminating the masses of infusoria from solutions to be studied under the microscope. These microzoa haunt even the clearest drinking water at times, and it becomes highly important to easily determine their presence. M. Certe (Proceedings Acad. des Sciences) suggests the use of osmic acid as a sure means of killing them without destroying their tissues. He dips a glass rod into the solution to be examined and then into a 1% solution of the acid; washing this in a narrow test tube of distilled water, it is easy to collect what is necessary for examination. There are certain precautions to be taken as to cleanliness and time of immersion. By the use of a mixture of Paris violet in diluted glycerine, he finds it possible, by uniform difference of tint, to easily distinguish cellulose, amylaceous matter and the vibrating cilia.

TERRESTRIAL MAGNETISM.—Prof. Balfour Stewart, in a letter to *Nature*, July 1, 1880, discusses the connection between auroras and magnetic storms. Since we have changes produced in stationary strata by a moving magnet, cannot the reverse be true? May we not have discharges produced in moving strata by a stationary magnet? The sun in this case would by convection currents produce changes in the atmospheric strata, and the earth as a permanent magnet would cause electric disturbances, which in turn would react upon terrestrial magnetism. Working upon this hypothesis Balfour Stewart has been led to the fact "that certain magnetic diurnal changes lag behind corresponding solar changes, just as meteorological changes would do," and he also states that his observations up to the present appear to show that an increase or decrease of solar activity corresponds to an increase or decrease of both magnetic and meteorological activity. The probability of a progress of magnetic phenomena from west to east, corresponding in character to a progress of meteorological phenomena is alluded to. Magnetic weather appears to travel faster, however, than meteorological weather.

Expansion of Glass by Heat.

Select a straight glass tube 50 or 60 centimeters in length and 1 or 2 centimeters in diameter. Place it transversely in front of a fire, in a horizontal position, properly supported near its two ends on two horizontally-adjusted rods of hard, smooth wood of about the same diameter as the tube; the glass tube will gradually roll towards the fire. Now let the supporting rods be transferred to either side of the center of the tube, so as to support it near its middle; the tube will now gradually roll from the fire.

It is scarcely necessary to remind the reader that the greater dilatation of the glass on the side of the tube which is nearer the fire renders it curved, with the convexity next to the source of heat, so that, when supported near the ends, the falling of the central parts of the curved tube rolls it towards the fire; but when supported near the middle, the falling of the ends of the similarly curved tube rolls it from the fire. These experiments, it is evident, succeed better when the cold tube is first adjusted near the fire than when it has been so long exposed to the action of the heat as to have become heated throughout its mass.

It seems that about the year 1740 this behavior of glass tubes under similar conditions was noticed by Mr. C. Orme, of Ashby de la Zouch, while heating some thermometer tubes. The Rev. Granville Wheeler, who carefully verified the experiments of Mr. Orme, very correctly ascribes the phenomena to the distortion of the tube due to the action of heat (*vide Philadelphia Transcript*, No. 476). Nevertheless, in the United States this behavior of glass tubes, when placed before a fire, has been frequently classed among the unexplained mysteries of glass! As recently as 1865, Mr. Deming Jarvis, of Boston, in his little volume entitled "Reminiscences of Glass-Making," p. 10 (2d ed., N. Y., 1865), refers to the phenomena, but with not one word of explanation. In fact, not long ago some of our semi-scientific journals characterized these phenomena as mysterious and inexplicable. Hence I have for the last 20 or 30 years employed such experiments, not only as exhibiting visible manifestations of the expansion of glass, but also as affording an instructive and significant illustration of how completely the most obvious mechanical results may be overlooked or obscured under the inspiration of the propensity to seek for the marvelous in nature!—*John LeConte, in Nature, August 5th.*

Curious Physical Phenomena.

A curious physical phenomenon has, says *Nature*, been lately described by Dr. Grassi in the Proceedings of the Royal Institute of Lombardy. An apparatus is formed of three concentric vessels with an annular space of about two centimeters between the first and the second, and the second and the third. The outer space is filled with oil, and the next with water. The oil is heated by a gas furnace to a little over 100°, and the water boils. Then hot oil at, for example, 150° is poured into the central space. This quickly cools to a temperature close to 100°. Dr. Grassi found that the central oil cooled more rapidly the higher the temperature of the outer oil; and with more delicate apparatus (in which the vaporized water was conducted and returned, and the outer oil kept at any required constant temperature) he arrived at definite numerical results, which he tabulates. With the outer oil at a mean temperature of 129.9°, for instance, the time of cooling of the inner oil from 130° to 110° was 49"; when the former was 105.1°, the latter was 57". Alcohol and ether gave more decided results. The maximum difference was obtained with ether; the outer oil being at 57.5°, the inner took 25" to cool from 57° to 50° (7.); whereas the former being 39.3°, the latter became 39.5". In all the experiments the cooling of the inner oil commenced at a temperature little above the maximum of the external oil. When the outer oil is at a higher temperature, at a certain point the heat begins to prevail, which is transmitted directly from the outer to the inner oil. An analogous phenomenon (to which Dr. Grassi refers) was that of some members of the Accademia del Cimento, who found that the water in a vessel surrounded by ice cools more rapidly if the ice be heated to accelerate fusion.

ENCROACHMENTS OF GREAT RIVERS.—The extent of the encroachments of streams like the Mississippi and Missouri upon their banks can only be compared with what is taking place upon the southeastern shores of Great Britain by the action of marine currents. Indeed, owing to the direct manner in which American rivers impinge upon their banks in certain parts, the destructive action is, in their case, still more rapid. Several thriving towns on the banks of the two rivers specified have within the last few years been swept away by the erosion of their banks. Some time ago, certain ingenious engineering processes, by which such disasters had been prevented, were described in *Iron*. In the case of one doomed town, Covington, in Iowa, some of these appear to have been tried but to have utterly failed, owing to the swiftness and depth of the current. Covington stands on a bend of the Missouri, which, in two years has, in one part of the town, cut into the solid land for a distance of 33 yards. Failing to stop the river, the Covingtonians are removing back their houses on rollers; but it is doubtful whether the site of the town will not have to be changed.

NORTH.—The South Hite company has made arrangements for the sale of a mill this fall.

ROCKY MOUNTAIN.—Hereafter all communication with the Crautery and Ferguson mines has been by the way of Coulterville and Sonora, but hereafter it will be by the way of Mariposa and Hite's Cove, a much shorter and more practicable route.

MONO.

BODIE DISTRICT.—Free Press, Sept. 9: There has been no developments in Bodie for some time. Since the Jupiter cut its rich body of ore on the 600 level, the company has not admitted visitors to the mine.

STANDARD CO.—Extracted and shipped to mill 1,135 tons of ore from the Bodie bar mine, and it seems that the shaft sunk 7 ft; total, 933 ft. The usual extension of work at all points has been made, and no change in character of ore or formation has been noted.

UNIVERSITY.—On the 605 level east crosscut extended to 33 ft; no change. West crosscut 38 ft, and nothing new in the 600 level south drift extended in total 313 ft and no change.

ROCKY MOUNTAIN.—Main shaft sunk 7 ft below the 600 level, where a station is being cut and drift started south, topping on the 550 and other levels progressing as last report, and Syndicate mill running.

BODIE CO.—Raising ore from the 200 level and sinking ledge to connect with level with the 300 level, is about all that is doing, aside from extending drifts on the 300 level and east crosscut.

ROCKY MOUNTAIN.—Main shaft sunk 7 ft below the 600 level, where a station is being cut and drift started south, topping on the 550 and other levels progressing as last report, and Syndicate mill running.

however, and is going to push the main tunnel ahead 500 ft further in the hopes of striking the channel.

PLUMBER.—The new 8-stamp crushing mill at Plumbago has been in running order for a couple of weeks. Several crushings have been made, all of which gave the most flattering results. The ledge varies from 2 to 4 ft in width. Only 5 men are at work now in the mine, but this force will be increased in a short time.

FLUORIDE PLAT.—The East ledge and Sears Union mining companies have closed up handsomely for the season. The last mentioned are through "for good," their ground being about worked out. The Bonanza, Virginia and California companies are working about as usual. It is reported that the last named companies have been bonded for handsome sums.

FLUORIDE PLAT.—Doubleday's *Mountain Messenger*, Sept. 11: Last week we visited the Forest quartz ledge, about a quarter of a mile from town. The property was worked years ago, but the owner became involved and the mine was closed. Since work has been resumed a very rich chimney 3 ft wide has been cut in the new tunnel. The quartz is full of gold, which can be easily seen by the naked eye, and yields \$1,000 per ton. This mine is owned by the Forest Co., of San Francisco. The company contemplates putting up a mill this fall.

NOTE.—Messrs. Hubbard & Darling brought to town, last week, some very nice specimens from their claim at the head of Floward creek. They have splendid diggings.

TRINITY.

BUCKEYE CO.'S DITCH.—Weaverville *Journal*, Sept. 11: We were informed by Mr. Helph, foreman of the work, that the Buckeye Co.'s ditch to Stuart Fork was completed on the 6th of the present month, and water turned in at the head on the 8th. It is expected that this will reach Owen's creek in a few days and connect with the water of that stream, which has been in the ditch for about 6 weeks. The entire length of ditch is in splendid condition, having recently been cleaned, timbered and thoroughly overhauled. The pipe across the river has been repaired and embedded in the bottom, is now substantial and in good running order. Some of the heaviest blasting ever done in this country was done on the last 2 miles of the Buckeye ditch, 50 rods being through rock, 10 rods through the rocky bar mine, and the rest through the ditch with Stuart fork being 3 ft on the bottom and through solid rock. The Buckeye ditch is the largest one in the county, it being about 40 miles, and covers much auriferous gravel. With the ditch through the river, the company will now have a full supply of water for mining purposes all the year round.

HYDRAULIC CLEAN-UP.—The superintendent informs us that the last clean-up of this company produced nearly \$10,000, making the total yield of the mine thus far this season about \$17,000. This is a splendid showing, as the ground worked had previously been drifted, and owing to a large slide, which interfered considerably, as much ground was not worked as would otherwise have been done. Everything considered the company is well satisfied with the result of the season's work, it going far toward proving their mine one of the best on the coast. With a liberal supply of water the yield would be enormous.

TUOLUMNE.

THE BONANZA.—*Independent*, Sept. 11: Recently this claim has had an accession of water, to overcome which they have cut a new ditch, and it is reported that the claim is still yielding immensely, and that in 2 days last week the owners took out \$100,000.

NOTES.—The Keltz mill is still running on good rock, and the vein is turning out good ore. A small diamond drill will be put at work immediately, to be run by the air compressor now in place.

SOUTHERN MINES.—*Cor. Independent*, Sept. 5: The new Williams process for treating rebellious ores is a perfect success and bids fair to make a revolution in the treatment of rebellious metals. The furnace is in good working order, and the tests have all proved favorable. Everything is ready to commence business. A rich chute of ore has been discovered in an old abandoned claim known as the "True Blue," which will be worked at once. They have struck a body of high grade ore in one of the drifts of the Osogood & Stanton ledge, and the best of good work, and everybody is on the tip of the tongue for the new developments that may arise from its use.

COLUMBIA AND VICINITY.—*Cor. Independent*, Sept. 7: Something like 4 months ago, a Mr. Osogood found rich lead rock on Five Mile Creek ridge, 6 miles easterly of Columbia, which led to the discovery, in a few days thereafter, of the Osogood & Stanton ledge, and a number of parallel veins in the immediate vicinity.

OSOGOOD & STANTON.—The owners have begun the development of this vein in good earnest. The prospect shaft is already down about 50 ft, showing the vein at that depth 4 ft wide. Walls are very regular. Formation, slate. This vein, taking the tests which have already been made, proves it one of the best milling veins in the county. The gold is evenly disseminated through the ore in every part of the vein, so far as tested.

OSOGOOD & STANTON EX.—This company has uncovered the vein for several hundred ft, and is driving a tunnel. Good bodies of millling ore have been found, and the vein is generally regular and of good size.

PARALLEL VEINS.—Since the discovery of the vein above mentioned, a number of parallel veins have also been found in the same locality, but that of the most importance, up to the time of writing, is a vein which T. C. Birney & Co. have located upon, which develops greater richness than the Osogood & Stanton ledge, so far as known.

NOTE.—Jacobs & Hart have located on the extension of the Birney vein. All the above mines are advantageously situated, as regards convenience of timber; and water, in abundance, can be had for milling purposes, at a trifling outlay.

NEVADA.

WASHOE DISTRICT.

SAVAGE.—Official Letters, Sept. 14: During the week we have advanced the face of the drift upon the 10th level 20 ft through porphyry carrying the stringers of quartz. Have repaired and retimbered 12 ft of the main shaft. Have completed the tank below the 2000 station, and have dug a drain and put in a drain pipe from the bottom of the 10th station to the level of the main incline. Have now commenced repairing and retimbering the 10th station.

EXCHANGERS.—The northeast diamond drill hole, 2000 level, is in 64 ft; formation, quartz and porphyry. We struck a large flow of water which forced us to stop drilling and plug up the hole. The north drift on the 2810 level is in 69 ft. The entire drift during the preceding week has been in quartz.

CON. IMPERIAL.—Have finished excavating chamber for diamond drill in crosscut west, 2810 level of Imperial, 350 ft north of south winze. During the week we have started a crosscut east of south winze station, which has been extended a distance of 28 ft.

OVERMAN.—Winze from 1000 level has been sunk 26 ft; total depth, 122 ft. Rock is somewhat harder. No increase of water. Incline upraise has been extended 32 ft. The ground is softer and working better. Forman shaft has been sunk and timbered 30 ft.

COLLAR.—Cutting out station at the 2400 level for hydraulic mining, and having completed the same for pumping engine. Engine transferred from old works and to be used in placing new pumps, etc., is in place.

OSGOD & CURRY AND BEST & BELCHER SHAFT.—We have sunk and timbered the shaft during the past week a distance of 25 ft; total depth, 1,580 ft.

BELCHER.—Making good progress in putting in new pump rod.

BRISTOL DISTRICT.

TEMPEST MINE.—*Pioche Record*, Sept. 4: There has been quite a strike in this mine, which adjoins the Hills. The leased Webster & Quigley, have struck a body of ore of the same quality as the rich ore found in the Hills.

BRISTOL CO.—The work in the mines of this company is being vigorously pushed ahead, and a large force of men is now employed. The mill is perfect, and does excellent

work. The roaster chloridizes ore in perfection. This company will soon commence shipping bullion.

STAR MINE.—At this mine everything is progressing as usual. Ten tons of ore are now being shipped, averaging \$15, and 60 in lead. A boarding house for the men is now being erected, and work upon the road is in progress. When everything is in working order, the shipments of ore will be increased, as this mine is showing great quantities of lead.

NOTE.—The refinery and furnace of the Hillsdale company are doing good work, the former turning out about 7 tons of bullion per day; coal and ore coming in fast. Another cupel furnace is under way and will be completed soon.

CHERRY CREEK DISTRICT.

STAR MINE.—*White Pine News*, Sept. 9: This is at present the largest and most populous mining district in the county. The Star mill is running steadily, and is turning out bullion regularly. About \$12,000 per week are being shipped; \$4,000 in bullion will be sent out by Tuesday's stage. The mine is looking exceedingly well.

TRACT AND GIBBS.—Work on these mines will be resumed soon, and we are positively informed that a 20-stamp mill will be erected by the company owning these mines this fall, if possible, and certainly next spring. They have ore enough now in sight to run 20 stamps for a year.

EXCHANGE.—A force of men has been put to work on this mine, and the 6-stamp mill is now being repaired, and as soon as it is ready to start up will commence working ore from this mine, a large quantity of which is in sight.

DUN GLEN DISTRICT.

LASS STYR.—We are informed by Gen. Crook, of Dun Glen, that a shaft was begun on the ledge of this mine from the bottom of the main tunnel, and in the course of a few ft the vein developed both larger and richer than it has been at any point above the level of the tunnel. The company cleaned up its mill the other day, and from a 10 days' run got \$2,250 in gold bullion.

EUREKA DISTRICT.

SILVER CONCOR.—*Sentinel*, Sept. 7: The new hoisting works of the Silver Concor are in splendid working order. Steam was generated in the boilers but a few days ago, and still the machinery runs as smoothly as that of mid silver, and from 55% to 60% in lead to the ton. It is a cut of 20 ft across the vein there are 14 ft of silver in the remaining 6 ft containing many seams of metal. The company is preparing to blast this immense body of ore, and have drilled holes ranging from 5 to 10 ft in depth.

GAOON CREEK DISTRICT.—*Prescott Miner*, Sept. 3: This district is so near Prescott that few of our residents even are informed of its great value. It contains a large number of locations, many of which have had considerable development, and yield high grade gold and silver ores. Among the claims which have yielded remarkable ore may be mentioned the Black Hawk and Gray Eagle.

NOTE.—Some time last spring Mr. Robert built a little brick furnace and smelted a few hundred pounds of galena ore, found in a streak in the Black Hawk and Gray Eagle claims. The smelting was not a success, but he gathered up about 8 lbs of the galena bullion in a frying pan and had Mr. Blake assay it. Blake's report, before me, shows the value of the bullion to be as follows: in silver per ton, \$556.05; gold, \$12,357.23.

WON RIVER.—Yauke Fork *Herald*, Sept. 4: We are informed by D. C. Coleman, who has just returned from this mining region, that the Mayflower mine is one of the most promising in the camp. It has been opened to the depth of 30 ft, and is yielding a good supply of shipping ore.

BULLION.—This claim is the first extension of the Mayflower, and has the same good characteristics. It is producing rich ore, assays of which run as high as \$2,000 per ton.

EUREKA.—This is a mine of carbonate ore of very high grade. At the surface the ore body is 2 ft thick.

NOTES.—The Treasury, Gphir and Lookout claims are being worked by the Bullion company. In the Treasury alone it is estimated that there are \$50,000 in sight. The company will push its developments this winter. The latest discovery was made by John Boyle, 3 miles southwest of Bullion. The vein has 3 locations on it, and crops out the entire 2 of them. It is 10 ft wide, and is set with sulphur, and assayed as high as \$5,000 per ton. Good judges say the rock will work as high as \$200 per ton. This strike is said to be the best on Wood river.

IDAHO.

WON RIVER.—Yauke Fork *Herald*, Sept. 4: We are informed by D. C. Coleman, who has just returned from this mining region, that the Mayflower mine is one of the most promising in the camp. It has been opened to the depth of 30 ft, and is yielding a good supply of shipping ore.

county, who are dependent upon custom mills to have their ore reduced, will see that the works are kept supplied with ore.

ARIZONA.

GLOVE DISTRICT.—*Silver Belt*, Sept. 4: We unhesitatingly pronounce the Richmond lode a genuine fissure vein. It is traceable, distinctly, a long distance. There are a number of locations on it, some of them being valuable properties. The W. Richmond, Stanton, Richmond, La Plata, Defiance, Mack Morris and Caro are on this lode. The Mack Morris uses only an electric of powder to make it vomit rich ore. It is the best developed of all the mines named.

ALBERT LEE.—Mr. Brecken brought us some very good ore, on Thursday last, from this mine. This property is near Chamberlain's big mine, and promises to become very valuable.

NOTE.—The owners of the Clyde have started a shaft on their property. It shows a solid body of low grade ore, larger than the shaft. The Nugget is turning out extremely rich ore, and the samples sent by Supt. Lennon back up the statement. We have been shown some wonderful ore taken from the Champion mine during the past week.

SAN SIMON DISTRICT.—*Tombstone Nugget*, Sept. 2: Mr. P. Ward has just returned from a trip to this mining district, some 30 miles beyond Ft. Bowie and a few miles within the borders of New Mexico. He and others have several claims located there upon which some development has been done, showing well and encouraging the owners to greater development. During the present trip Mr. Ward discovered a vein of about 3 ft in width and traceable for some distance which shows on top to be rich in both gold and silver. The railroad will pass within 3 miles of the mines and is now within about 5.

NOTE.—We learn of a number of persons who are preparing to take to the mountains on prospecting trips. This is the best season of the year for such pursuits. Grass is in the most luxuriant everywhere and water is more plentiful than at any other time of the year. Many are striking for the borders of New Mexico, and not a few are turning their steps toward the Mule Mountains.

SILVER DISTRICT.—*Cor. Phoenix Exporter*, Aug. 27: Great width of ledges is a conspicuous feature of this district. The property of the Silent Co. is notable. The ore from its immense vein ranges from \$104.97 to \$5,832 in silver, and from 55% to 60% in lead to the ton. In a cut of 20 ft across the vein there are 14 ft of silver in the remaining 6 ft containing many seams of metal. The company is preparing to blast this immense body of ore, and have drilled holes ranging from 5 to 10 ft in depth.

GAOON CREEK DISTRICT.—*Prescott Miner*, Sept. 3: This district is so near Prescott that few of our residents even are informed of its great value. It contains a large number of locations, many of which have had considerable development, and yield high grade gold and silver ores. Among the claims which have yielded remarkable ore may be mentioned the Black Hawk and Gray Eagle.

Progress of the Electric Light Abroad.

The fact that much more publicity is given in England and on the continent than here to the results attained by the promoters of the electric light, has given rise to the erroneous idea that little is being done here. Such is not the case, however. The applications of this light to the illumination, not alone of large spaces and of places of amusement, but also of factories and mills, are becoming more numerous. It is even rumored that Edison, of whom the public have lost sight entirely, has nearly completed works to test his light on a large scale in this city. The development in this country is steady and encouraging, because it is divested of all attempts to catch public attention by sensational reports. Abroad inventors are active and capitalists confident. The *Times* summarizes progress there in an able manner, but falls into the error of underrating the strength of the movement here. M. Gramme, who has done so much to aid this progress of electric lighting, is adapting his well-known dynamo-electric machines to the requirements of the Jablochhoff, the Werdermann, the Rappieff and other forms of the light. M. Jamin has come forward with a new light, and the Siemens light is said to be more than maintaining its reputation. The Brush light has been introduced into England from this country, and its use is extending. The Jamin light consists of three candles placed side by side, each candle being formed by two parallel carbon pencils held in a vertical position, so as to burn from the bottom. A bank of fine copper wire surrounds the candle and conducts the electric current, and is so arranged that the luminous arc is always kept at the lower end of the pencils. When one candle is burned out, the next is kindled automatically. Each candle burns two hours, and the cost of the carbon consumed is but a trifle over a cent an hour. A single lamp would thus burn six hours without requiring any attention, at an expense of not more than seven cents for material consumed, to which, of course, must be added the cost of generating the current. A Gramme machine, driven by an eight-horse engine at the rate of 1,500 revolutions per minute, sustained 12 Jamin lights, each equal to 32 candles. It was found that with a machine making 1,500 revolutions per minute, and a wire one-twenty-sixth of an inch in diameter, six lights could be sustained on a circuit of five-eighths of a mile; by doubling the size of the wire and increasing the revolutions to 2,000 per minute, a circuit of 10 miles can be operated. This light is in the hands of a French company with a capital of 8,000,000 francs, and one of its founders and directors is a man who is proprietor of about 60 gas works.

The most conspicuous success thus far has been won by the Jablochhoff system. For 18 months the Societe Generale d'Electricite, in contract with the Metropolitan Board of Works, have maintained the light on the Thames embankment without missing a single night. The lighting was recently suspended for a few days for the purpose of cleaning the engines, but has been resumed. It was found that a single 20-horse-power engine under the Charing Cross bridge could maintain as many as 80 lights between Blackfriars and Westminster, something over 2½ miles. The number of lights in actual use, however, is but 50, extending the whole length of the Victoria embankment. Experiments undertaken with a view to reducing the expense of this light have been attended with very gratifying results. The terms of this contract for the next 12 months are at the rate of 5 cents per hour for each light, and the illuminating power of each is equal to 378 sperm candles, but this is reduced by the ground glass globes to 265. The lights burn six hours, but can be burned eight. The Jablochhoff light has been successfully used for long distances and on a large scale, the Paris Salon having been lighted by it with 400 lights for two months. A Russian company has been formed, with a capital of \$4,000,000, to perfect and apply this system. A steam engine is being erected in the South Kensington museum for use in connection with the Brush light. A large court, formerly lighted by 1,700 gas jets, is now lighted by eight Brush lamps, at a cost of but 3s. per hour, a saving of 10s. per hour as compared with gas at the London price of 80 cents per 1,000 feet. Here, as well as at the British museum, the great advantage of the electric light over gas consists in the fact that it is perfectly harmless and void of danger, while the combustion of gas is destructive to paintings, decorative work and bookbindings. In a large biscuit factory at Bermondsey the light is found to possess the peculiar advantage of enabling the workmen to distinguish the most delicate shades of color, a matter of necessity in that business. Bass's brewery is to have a Brush light, and the company are about to erect works in the heart of London, intending to supply the light from a central point over a circuit of 10 miles wide. The Siemens light has been permanently adopted by the British Museum, and is in use on a large scale at the Victoria docks. The improvements recently made in the Gramme machine have increased the power of the Werdermann light, and its capability of subdivision—in which respect it is said to surpass all other lights—has led to

its application to domestic uses on a considerable scale in Paris. The supply of electricity is generated at a central point, and the light is laid on by wires wherever required with as much ease as gas. A Werdermann light equal to 300 candles, requires the use of only one-half horse power, and a 12-horse-power engine will maintain 30 lights each, equal to 300 candles. A notable feature of the progress made by all these lights is in reduction of operating expenses.

In conclusion, we may add that for European gas companies the electric light is losing much of its terror, not because of a conviction that its competition need not be feared, but because gas manufacturers are becoming confident that there is ample room both for the electric light and for gas. M. Jamin has made efforts to convince a number of representatives of the gas interest at Paris of the absence of any danger to its future growth and prosperity. From the language of one of its number, M. Jordan, it appears that they are beginning to take that view.—*Iron Age*.

A Remarkable Clock.

Probably the most ingeniously-contrived piece of mechanism in the late fair was the clock which was invented and constructed by Mr. A. Jackson, of this city. Mr. Jackson is quite an inventor, this being only one of his devices. This he calls a "pantologue," and is the result of three years' study. It is in the Art gallery near the stairs. The clock stands in a case over 10 ft. high. At the base is a globe completely mapped, giving the daily recurring motion of the earth. A hollow shaft on the axle carries the moon around the earth in its due proper course of time. The moon, which is half bright and half dark, keeps this bright side constantly to the sun, showing its various phases in the course of its journey around the earth—showing at full moon its bright side to the earth, and at the first and third quarters the half moon. Over the globe is a dial, divided into 24 equal parts, signifying the 24 hours, and painted to show sunrise, noon, sunset and midnight. To the left is an aquarium filled with water and containing living goldfish; and in the aquarium, by means of a scale, the rise and fall of the tide in San Francisco each day, with its variations, are demonstrated to a nicety. A large gold ball projecting from the mathematical center of the picture is the sun, and affixed to the sun, and revolving around it in proper rotation, are the planets, keeping, in their revolutions around the sun, their bright side to and their dark side away from it, showing day and night in each planet. A look at the painting will explain what constellation any one of the planets is in at that particular time.

There is also a calendar on which is presented the month, day of the month, and day of the week. It takes care of February very nicely. Two minutes before each hour, the figure of a messenger boy emerges from a door on the right of the clock, bearing in his hand a card marked "Time," and comes to the center. He remains standing for a little while, when Winter passes into the little cabinet door, and Spring again appears. The little bell does not strike this hour, that being struck by an electric bell in the tower, on the left-hand corner of the clock. This bell is struck by an operator, sitting in a niche, who telegraphs the moment when the messenger boy is to appear. To the right, about three ft. distant, and attached by a narrow brass rod, is an independent electric clock, admitting a current to the main clock every minute, and, though separate, governing the motion in the main instrument. To the pendulum of the electric clock is attached a thermometer, showing the average temperature, and a barometer showing the state of the temperatures. In the base of the clock is a musical box, playing a number of airs with flute accompaniment.

CHOKED STREAMS IN ENGLAND.—It seems that the English are now contemplating relief from ruinous overflows occasioned by the filling in and shoaling of their rivers. Their trouble is, however, in much milder form than our debris difficulty. We read in *Iron* that at least two palliatives suggest themselves. The lower courses of the rivers which flow eastward ought to be kept open by dredging. The Ouse, for example, is stated to be getting gradually choked with silt and weeds, so that, unless vigorous steps are taken to clear it out and keep it clear, the whole fertile valley will by and by be subject to the passage of flood waters without control. Another obvious step is the formation of reservoirs. The mean rainfall is perhaps not much in excess of the requirements of the crops, and in many parts of this country—for example, in the valley of the Thames—such a provision, in a season or two of drouth, and these come in sets, would repay much of the cost of the works; for it is estimated that last summer, in the valley of the Ouse alone, the occupiers of the land suffered a loss from floods of at least \$500,000, and it is believed that the losses sustained in the other valleys of the country were not, in proportion to their area, at all smaller.

More than 125,000 children die in France before reaching the end of their first year. One-fifth of the entire number are in Paris. In the arrondissement of Nogent-le-Roi, where mercenary baby farming is common, there are 52 deaths in every 100 children under one year of age.

Sleeping in a Volcano.

When all the stragglers had come up, a consultation was held, and it was decided that it was too late to go down that day, and that we must spend the night in the crater. Waving adieu to the world, we clambered down the wall of ice, and found ourselves on a narrow strip of warm sand, overtopping what is known as the interior lip. From this point there is a treacherous descent of seventy-five feet to the point where the wall of the crater becomes abrupt and perpendicular; and here, on an overhanging rock, is planted a rickety old windlass on which the sulphur miners ascend and descend. The windless is worked by hand. There is no cage or basket at the end of the coil. You are tied into a loop at the end of the rope, like a box of sulphur, and lowered away over the smoking abyss, the bottom of which is 300 ft. beneath you. One by one we were lowered over the precipice in this manner, and then commenced a most treacherous and difficult descent over the sloping pile of debris, from the base of the precipice, 1,500 feet down the very bottom of the crater, where the only place of safety is to be found. We had hardly commenced this perilous descent when a tremendous report saluted our ears, and a hundred tons of rocks went crashing past us on the left and rolled into the bottom of the chasm. This was a mode of salutation that we had not anticipated, but it soon became evident that the ability to dodge rocks was the only guarantee of safety here. Owing to the alternate action of heat and cold, the sides of the crater have become completely rotten, and during the heat of the day immense quantities of rocks are constantly falling. Toward morning they freeze in again, and all remains quiet for a while. During the past twenty years many men have been killed on this spot by these avalanches of stones. In order to protect themselves, the sulphur miners have built little huts in the crevices among the huge boulders at the center of the crater. Some dying convulsion swelled up a little mound at this point, and only the larger boulders, falling from the highest peaks, ever reach it. There is still danger on one side, however, from ordinary stones, and when that startling word, *pedra*, rings out through the chasm, the men come swarming out of the minas like a flock of quails, and hide themselves in well-known places of safety. On entering the crater no one escapes the dread malaria of the spot. Indian and white men alike go down, with flying pains in the head, and a nauseating feeling at the stomach that is worse than sea-sickness. Conklin, of our party, seemed most affected. He had strength enough to crawl to one of the huts, and there he sank down on a mat in an almost insensible condition. It was not long before the rest of us joined him, and then commenced one of the most unpleasant nights I ever spent. Seven of us were confined in a space of about six by seven feet. It was impossible for any man to stretch himself out to full length. Nearly all of us were deathly sick, and combined with these discomforts was the constant fear of being crushed by the falling rocks. All night long they fell with fearful reverberating echoes from the surrounding cliffs. We were told that more than usual came down, owing to the fact that the preceding day had been a little warmer than common. In contrast with the booming sound of these flying boulders, came the sucking, snoring sound of the great *respiraderos* all around us. These breathing holes, or vapor-jets, are six in number. They are in constant action, and throw off immense quantities of smoke and vapor, with now and then a lurid tongue of flame. All the heat of the crater is not confined to these spots, however. Little jets of steam creep out from every crevice, all the rocks are warm, and it is impossible to find a place to lie down where you are not tormented by curling whiffs of sulphur smoke rising from the earth beneath you. Toward midnight I found it impossible to endure my cramped position in the hut any longer. Every muscle in my body ached, and, as sleep was out of the question, I gathered up my blanket and made my way out into the open air. A scene of the most weird and awful character presented itself. The crater seemed full of smoke. Detached clouds of vapor waved themselves back and forth along the cliffs like ghosts, and as I listened to the hoarse breathing of that mysterious power which I could not see, I thought of the wild Aztec legends connected with the spot, and, in my superstitious mood, I half believed that the restless spirit of their departed chiefs had risen to confront and haunt me for my intrusion into their dread abode.—*D. S. Richardson in September Californian*.

The influence of very small quantities of foreign substances in modifying processes of chemical change is a subject of much interest to the chemist, although as yet no full explanation has been given of this class of phenomena. In the course of his researches at high temperatures, Victor Meyer has given one or two instances of such reactions. Thus he finds that ferric chloride, aluminium chloride and zinc chloride are decomposed with evolution of chlorine at much lower temperatures when the vapor-density apparatus is previously filled with nitrogen gas than when no foreign gas is present. Meyer cannot trace any connection between the temperature, or amount of decomposition, and the chemical nature of the foreign gas.

What Vivisection Has Done for Man.

Dr. Charles Richet, in a vigorous defense of the practice of vivisection, demands that it shall be judged by its practical results, and claims that, if it can be shown that we have gained by that method of experiment the means of curing one or two diseases of man or of assuaging pain, it must be considered lawful. He cites a number of discoveries that have been made through vivisection to sustain his position. Among them is the discovery of the circulation of the blood. Galen established the fact that the arteries contained blood by observations in the artery of a living animal; Herskovy opened the chests of living animals, cut into the pericardium, observed the contraction of the heart, and what was going on in the veins and arteries, and deduced from what he saw his theory of the circulation. Transfusion of blood, an operation resorted to in extreme cases with the best results in saving life, was introduced after its possibility had been ascertained from experiments upon animals first made in 1664 by Lower, and afterward by Denis. "Experiments alone," Dr. Richet says, "will teach us precisely what quantity of blood is necessary and what is harmful; and if over-sensitiveness forbids animal suffering for this end, then the experiments would have to be made on human beings." The mode of death from the inhalation of carbonic oxide, and, correlatively, the method of avoiding or preventing death from inhalation, have been made known only through vivisection. So also "all that we know in hygiene of the quantity of air necessary to support life is the result of experiments on dogs and rabbits. Sometimes a precise knowledge of the conditions of respiration has served to prevent men from perishing." Only two methods exist by which we may learn the conditions of gastric digestion and collect its secretion, viz., by observation of gastric fistulae produced by chance in man, and by artificial fistulae in animals. The first method has been possible only in three or four instances, but the effect of food on the gastric secretion in dogs and cats has been largely observed; and the knowledge of the remedies which have been applied to the relief of dyspepsia has been derived from such studies. Our knowledge of nutrition has been largely added to by means of experiments in which dogs and cats have been submitted to varied alimentation, and from which the quantity and quality of food necessary to sustain life have been deduced. What we know of the nerves has been gained from studies of animals, as have also the means of relieving neuralgias and paralysis, in which, thanks to the scientific analyses of the vivisectioners Fritzsche, Hitzig, and Ferrier, "we can pass from this effect to the cause, and assign to paralysis a central lesion at a well-determined spot, so that trephining at this spot may cause the paralysis to disappear." The experiments of Galvani and his followers on frogs have taught us to estimate the effect of the electric current on nerves and muscle, and shown us how to apply galvanization to the prevention of the paralysis which ensues from the destruction of the motor nerves. The numerous patients relieved of nervous diseases "by this admirable therapeutic agent have no call to speak ill of such vivisectioners as Galvani, Aldini, Volta, Magendie, Marshall Hall, Remak, Du-Bois Reymond, and many others, since it is to their discoveries that the relief of their ills is owing. Would Galvani have made his discoveries had he refrained from dissecting frogs? Would the electric current have been applied to atrophied limbs if it had not been found that the action of this current in dogs was salutary and not dangerous? Certain diseases of the urinary organs have been studied in animals. The treatment of sympathetic ophthalmia by section of the ciliary nerves of the diseased side has been shown to be advantageous by experiment, and the results yielded by experiments on dogs and rabbits have been applied to patients. The correct treatment of cataract has been similarly learned. Encouraging progress is made by vivisection in the study of the formation of callus, of pseudarthrosis, of osseous grafts, of regeneration of bones by periosteum, subjects of great importance in surgery. The vasomotor theory, which plays a large part in the medicine and surgery of the present day, has been established by experiments on the great sympathetic and the rabbit's ear. Dr. Brown-Sequard has furnished useful ideas relating to epilepsy and tetanus from the results of painful experiments on dogs and Guinea pigs. Trial on animals is useful to determine the action of new medicines, for "we do not wish to experiment on man at the risk of poisoning him, where animals can be employed," so with poisons. Finally, if we deprive savants of the right to submit living animals to experiment, we shall go back beyond the days of Galen. "If all those who have been relieved—verily made to live again"—says Dr. Richet, "by modern medicine and surgery, could speak, they would confound those who load vivisection with calumny, and they would hold that their own life and sufferings weighed more in the balance than the sufferings of those animals which have been sacrificed in laboratories to the lasting benefit of man."

M. POINCARÉ has presented to the Academy of Sciences, Paris, the results of an investigation of butcher's meat, in which he found cylindrical pointed elements with cuticles crossed by lines which seem outlines of cells, and which appear granulated. He thinks they may be phases or metamorphoses of tanioids, causing tenia in some eaters of raw meat.

Improvements in Traveling.

It is only by means of comparison, says the *New York Times*, that one can definitely realize the great improvements in the method of traveling that have taken place within the present century. The changes occur so gradually that they make but little impression upon us. For example, now that the railroad time needed to make the trip between this city (New York) and Philadelphia has been reduced to less than 100 minutes, there are already those who are predicting that in no more time than five years trains will cover the distance between these two cities in a single hour, and no one is the least surprised at the assertion. In 1800, those who traveled in this country did so on little personal discomfiture, and with an expenditure of time that would greatly interfere with business as it is now carried on. A man wishing to go from this place to Boston left Moudry forenoon and arrived at his destination on Friday afternoon, stopping all night at New Haven, New London and Providence. The fare for the trip varied from \$15 to \$18, and there was an additional outlay required of from \$5 to \$6 for board and lodging; that is, the trip took up four days of time and called for an outlay of from \$20 to \$24. After the war of 1812 there was an improvement, and the time between this city and Boston was cut down to about two days, and the cost of the journey to \$14. In 1817, the fare between New York and Philadelphia was \$10, and between New York and Albany by boat \$7, and the average time 24 hours. A route was that year opened between Philadelphia and Quebec; the distance 700 miles, fare \$47, and time required to make the journey 103 hours. In 1826, the Boston newspapers recorded the circumstance, as one worthy of special comment, that New York papers had been received in that city in 24 hours after the date of their publication. In 1828, the time required to make the journey between these two cities had been reduced to 21 hours, the route being from this city to Providence by steamboat, and from thence to Boston by stage. But in winter these trips were frequently given up in consequence of stormy weather, and those who wished to avoid danger and be certain in their movements still preferred the overland route. In 1832 there were two regular stage lines between this place and Boston, but competition had greatly reduced the fare. The slow line made the distance in about 52 hours, and charged for passage \$7.50, while the fast or mail line took its passengers through in about 45 hours, and charged them \$8.50 a trip. A short time after this the railroads came sufficiently into operation to make it unnecessary to run through trips in stages, and the latter were chiefly used to connect the termini of the slowly building railroads. Having made the progress that we have, there is not the least likelihood that the work of improvement will not go on. The history of railroad accidents show that, while trains on some roads run at a slow rate of speed may meet with mishaps, there is relatively little danger in running at the highest possible speed on a road that is thoroughly constructed, where the appointments are as nearly perfect as possible, and the supervision constant. On this account one does not have to be unduly sanguine to think that long before the century is out we shall be able to go from Jersey City to Philadelphia in an hour's time, and from the Grand Central depot to Boston in a less number of hours than the number of days spent by our ancestors, in the year 1800, in making the same trip.

COLORADO COAL DEPOSITS.—A late number of the *Leadville Chronicle* contains an account of immense deposits of coal at Canyon City, the discovery of which is of great importance to the smelting operations of Leadville. These coal fields, it says, are more than 50 square miles in extent, with working veins extending through 800 ft. as tested by diamond drills. The workings at present actively employed range from one and a half to 10 miles, and are now producing 800 tons daily, which may be increased without extra expense to 2,000 tons. Experts pronounce it the best of coal for all locomotive and other machinery. From its surplusage of pure carbon and freedom from sulphur, it is believed to be adapted to any kind of smelting and reducing process. It can be delivered at Canyon for \$1.75 per ton. The Atchison, Topeka and Santa Fe Railroad Co. are constructing a broad gauge coal road from Pueblo to the coal lands of the Grand Canyon Coal Co., which will be completed within a short time. Two-thirds of the demand of the whole State, which is at present 1,500 tons daily, it is claimed, can be supplied from here, and at present the daily output ranges from 700 to 900 tons. All the coal of the Canyon district is easily worked. It is bituminous in character, and of the best quality, and readily sells for \$2 per ton more than any other coal in Colorado. It will not slack or decompose when stacked or corded. The lower vein is fully 5 ft. thick, and all coal taken therefrom is of the first quality, free from slate or other impurities. It needs no timbering, as the cap-rock is very firm. It is here, very evidently, that Leadville's future supply of cheap fuel must come from, unless the remaining locality, that of Como in the South Park, should prove to be still more available.

PAPER STOVES are the latest development of German ingenuity.

USEFUL INFORMATION.

To Distinguish Dyes in Colored Goods.

It is often necessary to know with what coloring matters a pattern has been dyed. In some cases an experienced dyer can soon ascertain, almost at a glance, or by simple methods, which dyestuff has been employed; but with many colors this is sometimes impossible. Especially is this the case with blue dyed fabrics, in which it is not easy to say whether a pattern has been dyed with vat indigo alone, or has been topped with cheaper stuff.

The detection can be made by a chemical analysis, the method consisting in destroying one of the coloring matters by some reagent, and thus prove its existence by the use of this destroying medium. To ascertain which mordant has been used, it is only necessary to burn a certain quantity of the fabric, and to find out by chemical analysis which oxide was present on the fabric. These methods are, however, only of use to chemists; but the following is a simple method that may be employed by anybody to determine the coloring matter. To begin with blue dyed fabrics. *Vat blue*, in the first place, is neither affected by alkalies nor acids (with the exception of nitric acid). Only chlorine and chlorino compounds react on vat blue.

A blue dyed with *sulphate*, or *extract*, or *carmine of indigo*, is readily abstracted by boiling water, and even more so by caustic alkalies.

Prussian blue is easily recognized by using alkalies which destroy it, while chlorins and acids have no effect upon it. However, the alkaline chlorins compounds of commerce (bleaching powder, etc.) react upon it.

Goods dyed with *logwood* give, with acids, a coloration more or less yellowish. In case there is another color associated with logwood, this latter may be extracted with a large quantity of acid. The fabric is then well washed, and the remaining color examined.

The red colors are more difficult to determine; but these colors have not the same importance as the blues.

Colors dyed with *cochineal* and *Brazil wood* (which, however, every dyer can easily distinguish) become gooseberry red when treated with muriatic acid. If it is washed, and then passed through milk of lime, a pretty loose violet is obtained. *Madder red*, treated exactly in the same way, and after the milk of lime bath boiled with soap, acquires a more intense color.

Cochineal red and *Brazil wood red* can be easily distinguished by means of oxalic acid, cochineal red becoming brighter, while the other is more or less destroyed.

Black, which is generally dyed by two methods, either with iron or chrome, when treated with chlorins, is destroyed if dyed with iron; but, if a chrome black, resists to a certain extent, only becoming chestnut brown, even with strong treatment.

To distinguish other colors there are many methods, which are, however, too complicated to be mentioned here. Aniline colors require greater chemical knowledge to distinguish them from each other.

ALLOY PRESERVATIVES.—It is well known that the action of a third party, however slightly electrical, may modify catalytically the electro-chemical action of two others. This electro-chemical fact has led to the arrangement of a great number of alloys of various atomic proportions stated to be non-oxidizable, but as the nature of the reactions of such alloys upon their own oxides is not thoroughly understood, the production of the long-sought-for non-oxidizable alloy protector has not as yet been completely realized. Certain alloys, however, are said to possess great merits as electro-chemical preservers of iron. The alloy composed of 23 parts of zinc and 8 parts of copper, has been proved by experience to possess a minimum factor of oxidizability, and to be a great preservative of iron and steel. The alloy proposed by M. Soriel is stated to be almost unoxidizable, equal to iron in hardness and more tenacious than soft iron. The alloy is composed of 80% of zinc, 10% of copper, and 10% of iron.

The floating of birds on and with the wind does not appear specially mysterious. It is now recognized that a breeze of air is a succession of denser and denser volumes, rushing in to supply the place of comparative vacuity, and thus to maintain pneumatic equilibrium. Passing along the surface of land or sea, this succession of densities possesses the properties of a wedge, tending to lift from the ground objects whose specific gravity is greater than that of air. Thus, on a windy day, thistledown, feathers, straw, paper, may be seen floating on the "wings of the wind;" and should the gale increase to a hurricane, trees, roofs and even cattle may be lifted from the earth. Inanimate objects being in this way capable of sustentation, it is not surprising that a bird can adjust its wings in such a way as to appropriate to the full the floatative power of the wind.

TO RELIEVE CASKS FROM MUSTINESS.—Burn a little sulphur in the empty casks, bung, and let them stand for a day.

A SERIES of experiments is soon to be made with Capt. Ericsson's new system of submarine attack.

ARTIFICIAL PEARL.—M. Duvochel has invented a compressed kind of nacre or pearl, made of the pulverized shell of the halotis, solidified with gelatins. Thus prepared it will serve for inlaying or mounting in cabinet work, cartonnage, tablature and other industries, and the manufacture of fans, buttons, etc. This product can be figured, stamped, molded by pressure, poured out in the liquid state, and, in fact, takes every kind of form desired. It can be dyed in any color, polished and varnished by the processes used for tortoiseshell, mother-of-pearl and other analogous substances. To render the shells thin and friable, they are submitted to a strong heat, which separates them into thin scales; these are then pressed in the cylinders of a flattening roller, and afterward pounded in a mortar. It is then sifted to get rid of the dust, and this powder is treated with gelatine, and formed into any shape required.

TO TIE THE COTTON CROP.—About 75,000 miles of hoop iron—enough for a three-fold girdle around the earth—will be needed to bind the forthcoming cotton crop, if it reaches the number of bales predicted by statisticians, or 6,000,000 bales. The number of bands required is six to a bale, or 36,000,000 in all. They are of uniform size, 11 ft. in length, and 1,200 weigh a ton. Hence there will be required 30,000 tons of hoop iron. Cost about \$3,000,000.

THIN GLASS COVERS.—A microscopist has taken the trouble to measure the thin glass covers purchased at a first-class house, and found that in two ounces but 4 were correct in their thickness 1-150 to 1-200 of an inch, 4 belonging to a cheaper grade. Only 1-68 were 1-200 of an inch in thickness, the majority being only fit for opaque objects.

MERCURY AND LEAD.—If a piece of lead wire be hung perpendicularly over a vessel of mercury, the lower end immersed, the mercury will gradually permeate and ascend the wire to a height of three ft. in a few days.

GOOD HEALTH.

Dr. Tanner's Great Task.

It should not be his lost sight of, says the *Scientific American*, that the fasting of Dr. Tanner was very different from cases where a fast is held by necessity, such as being compelled by disease, by shipwreck, by being lost in a wilderness or forest, being hurried in a mine, or lost in a cave. Dr. Tanner had enormous advantages over all these cases, and hence, he could indulge at once in hearty meals, as his digestive apparatus was not impaired by disease, nor his nervous system shattered by anxiety; in such cases it would be very dangerous, if not fatal, at once to indulge immediately in such abundance of food. In the case of shipwreck, the exposure of the survivors, resulting in a total want of any comfort, but to the enduring a suffering from other distressing discomforts, and exposure to the elements, contributes as much if not more to the fatal results than the need of nourishment. To this must be added the anxiety and uncertainty which keeps the nervous system upon an exhausting strain. It is the same with those being lost in a wilderness or forest. Of these the forest gives the best chance of survival; but in case of burial in a mine, the utter want of light and the gloom surrounding the victim, combined with the extreme anxiety, make a fast under such circumstances the most destructive to the nervous system. Persons who, for instance, were lost in caves, such as frequently happened in the Mammoth cave, were, after only a few days' search, found to be nearly insane, so much so that they hid themselves from the searchers.

It is evident that Dr. Tanner had an easy time, if his fast is compared with that of any of the fasters for causes mentioned above. If he had been locked up under threat that no food would be given him for 40 days, he surely would not have stood it so well, as the mere consciousness of the constrained situation would have affected his mind, and all ease and comfort would have been at an end. To the contrary, his mind was kept at peace because he had plenty of air and water, the comforts of good shelter, and all the conveniences of life.

These facts were overlooked by those who from the first declared a 40 days' fast an impossibility, and staked money on it. They were not well informed about actual fasts for so long a period, of which there are instances on record, or they did not believe the truth of such records.

Dr. Tanner may not have proved that everybody can fast 40 days, but if he has only proved that man can fast longer than has generally been supposed, that we are all eating too much, and that for a family remedy, fasting affords a better, safer, and more economical cure than the taking of all sorts of patent medicine, to which many people are so much addicted, he has done a really good work.

WHAT CAME OF JUMPING THE ROPE.—Dr. Peck, of Indianapolis, has amputated the legs of a young girl on account of decay in the bones, produced by excessive rope-jumping. He advises parents and teachers to prohibit this play under all circumstances.

May Girls Jump the Rope?

A surgeon in a Western city has published an article designed to warn parents against allowing their children to jump the rope, an amusement of which they are very fond. His objections to this exercise are that it produces a continuous concussion of the joints in the spin column of a dangerous character, often resulting in inflammation and necrosis of the bone, deformity and death. He concludes by saying: "I would warn children against rope dancing, and advise parents to prohibit it under all circumstances." His opinions are founded on the fact that he has seen very bad results from the practice. While we do not doubt that jumping the rope may be carried to a dangerous extent, we deny that it is a dangerous exercise. It is only when carried to too great an extent that it injures, or when practiced by very delicate children longer than it should be. Children in their sports are apt to go to extremes, and here lies the danger. How many thousands of children have lost their lives by eating too much food, or eating unwholesome food, and yet we do not prohibit our children from eating, but try to teach them how to do it right. Many children lose their lives in the water, yet we continue to teach our children to swim, and shall to the end of time. Children become injured by jumping the rope, and the wise course is to teach them not to go to extremes in this or any sport. Jumping the rope is of itself a perfectly safe exercise. It is one that children enjoy. It cultivates all the lower parts of the body in a remarkable manner, giving skill and grace of movement. Mothers need not prohibit it, but only watch their children so they shall not go too far in its practice.—*Herald of Health.*

HYSTERIA.—WHAT IS IT?—What is hysteria? asks a young lady who says some day she will study medicine and be a physician, even if for no other purpose than to know about the body, so wonderful in its make-up and its action. In reply we may say that hysteria has been defined in many ways by many physiologists, but in our opinion most of their definitions are faulty in many ways. Hysteria is a sort of nervous strain, in which nervous action breaks over all restraint of the will and the judgment, forsakes its normal course and gives rise to incoherent, unnatural, irrational ravings. Hysteria is a sort of insanity. The forces in the nervous system, like the forces in nature, are subject to various disturbances. In nature they break out in thunder-storms, hurricanes, etc. In the human body we have instead, hysteria, passion, and other phenomena. If we could control the distribution of heat and cold in nature, we could modify or do away with violent cosmic changes by equalizing everything. The same would prevent hysteria. Equalize the circulation of the blood in the human body and hysteria would rarely if ever appear.—*Herald of Health.*

THEY HAD ALL HAD IT!—A health officer writes to a Canadian medical journal as follows: "Inspected a house in the country at the request of the attending physician, as the general health of the family had been bad for a long time, they having suffered from a class of complaints that would indicate bad drainage, etc. Found under the floor a wooden drain with rotten cover, and soil saturated with sewage; trap on water-closet non-effective; water-closet foul; situation very bad; ventilation so arranged as to poison the room above it, a sleeping apartment occupied by a young man suffering for a long time from general ill health. No trap on kitchen sink; water supply, cistern connected directly with the sewer without traps in the overflow pipe. On my reporting the latter fact to the family, and expressing my surprise that they had not all had typhoid fever, they exclaimed in chorus, 'Oh, we have all had it!'"

It is a sin to be sick, says an exchange, unless the illness is hereditary, and sickness is reformatory punishment of violated law, always. But "In knowledge there is power," and in order to make people healthy they must learn the laws of health, and the results of disobeying them. In every walk of life there is need of more self-knowledge. The most enlightened sometimes touch the harp strings of life too roughly, and the harmony of sound is soon destroyed. But ignorance, self-will, gratification of appetites and passions have kept misery in the world, and probably will continue to cause disease and untimely death for many years—at least until we reach a higher plane of intellectuality, and learn to live simply and in obedience to hygienic laws.

HOW SHIPS ARE DISINFECTED.—The following system of disinfection is recommended by the Austrian government for vessels that had cases of small-pox on board: Sulphur to the extent of 12 grains per cubic meter of space to be disinfected is to be burned in an earthenware basin, placed in the center of some sand to prevent all risk of fire. All the linen, clothes, etc., are to be hung across the cabin, which is to be hermetically closed for three hours, and afterward exposed to the strongest possible drafts of air for 12 hours. Then the walls, floor, ceiling, etc., are to be washed with one kilogramme of lime or one-half a kilogramme of chloride of zinc to every hundred liters of water.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—A New Hot Air Engine; A Premium for Improvements; Inventor of the Telephone, 177. The Week; Emotional Economy; Registering the Cost of Mental Effort; Rare Gold Quartz; Insuring Miners' Lives, 184. Silkworm Culture in America; Value of the Diamond Drill; General Albert J. Meyer; The Phonograph—Sound Reproduced by Light, 185. Discovery of a Submarine Plateau; Tricks of Charlatanny; Tahoe—Origin and Meaning of the Term; List of U. S. Patents; Notices of Recent Patents, 189.

ILLUSTRATIONS.—Erickson's New Caloric Pumping Engine, 177. The Late Gen. Albert J. Meyer, Chief of the Signal Service Bureau, 185.

CORRESPONDENCE.—Mines of Owyhee County, Idaho, 178.

MECHANICAL PROGRESS.—High-Speed Machinery; Iron in Architecture; A Shower of Railroad Spikes; Hollow Ground Razors; A Difficult Piece of Casting; Hardening Glue, 179.

SCIENTIFIC PROGRESS.—The Cause of Perpetual Snow; Disease Organisms; Terrestrial Magnetism; Expansion of Glass by Heat; Curious Physical Phenomena; Encroachment of Great Rivers, 179.

USEFUL INFORMATION.—To Distinguish Dyes in Colored Goods; Alloy Preservatives; Artificial Pearl; To Tie the Cotton Crop, 183.

GOOD HEALTH.—Dr. Tanner's Great Task; May Girls Jump the Rops?; Hysteria—What is It?; They Had all Had It; How Ships are Disinfected, 183.

MISCELLANEOUS.—A Rich Auriferous Belt; Boiler Explosions by Mysterious Agencies, 178. Progress of the Electric Light Abroad; A Remarkable Clock; Choked Streams in England; Sleeping in a Volcano; What Vivisection Has Done for Man, 182. From Vera Cruz to Mexico, 186.

NEWS IN BRIEF.—on pages 189 and other pages.

MINING STOCK MARKET.—Sales at the San Francisco Stock Boards, Notices of Assessments, Meetings and Dividends, 180.

MINING SUMMARY.—from the various counties of California, Nevada, Montana, Arizona, Utah and Idaho, 180-181.

Business Announcements.

The Week.

This is the season of fairs. The fair of the Mechanics' Institute closed in this city last week after a successful course of five weeks. The receipts were about equal to last year's exhibition, which lasted one week longer. The fair, or rather, the industrial exhibition, is, if wisely conducted by practical men, an efficient stimulator of ambitious enterprise, and at the same time a pleasant way of educating the youths of the State.

Since its arrival in this city the Presidential party has in the main enjoyed itself in a quiet and unostentatious manner. Among other notable places, the President visited the Chinese quarter, and saw the yellow man in the parlor as well as in the slums. According to the report of the visit, the filth and naughtiness disclosed were almost unspeakable; and it would seem that the President must have felt himself impelled to utter a summary veto.

At present general business both in the city and the State is dull. The Presidential campaign has been fairly opened, and popular interest is absorbed in the political struggle. The shadow of the contest has already fallen upon the interior towns, and now politics, and not mines or farms, burden the columns of the papers. After November there will come a sharp reaction, and all forms of industry will move the brisker after the temporary lull.

A VETERAN DIGGER.—In a report of a field trial in Australia we read: The digging match created no little interest, from the fact that a gentleman nearly 70 years old entered as a competitor, three young men having had a start of about 10 minutes. He, however, carried off the palm, making a much better and earlier finish than either of the younger competitors.

A COMPANY has been experimenting in Florida with palmetto for making paper with such gratifying success, that they will build 20 paper mills in various parts of the State.

Emotional Economy.

There is in every community a class of people, well-meaning and generally zealous, which looks at and approaches all questions through its emotions, and decides affairs of the greatest moment by its warm feelings rather than by its cool reason. The very earnestness and zeal of this class is often a menace to some valuable interest or beneficent industry. These lively people seem never to consider that our systems of economy, whether social or political, are based upon the best experience of the civilized world, and have been tested by the severest practical ordeals. Evils abound, unfortunately, in every community, and it is the province of intelligent men, and no less their duty, to endeavor to trace them to their sources and to suggest or point out the appropriate remedies. But these emotional economists seldom scent an evil with a "cold nose;" they no sooner perceive an evil, the existence of which every rational man deplores, than they gush and bubble and boil with emotional wrath, and would incontinently pluck it up by the roots. Under the conviction that they do well to be angry they would destroy without reason and without intelligence, and for every devil they cast out they would put a dozen in possession. There are many examples in point.

In this city not long ago, one who is devoted to the cause of temperance—that is, abstinence from alcoholic drinks—declared in a public lecture that he was unspeakably glad because of the presence in California of that pest of the vineyard, the phylloxera; and he expressed the hope that the last vine in the State would be destroyed by its ravages. He would be delighted, he said, to see grain fields take the place of vineyards, to the end that the accursed traffic in wine might be destroyed. The strong emotions of the lecturer stamped his rational faculties, and the reform he proposed for an alleged evil would introduce a score of grosser ones. This mode of thought seems like a form of mental disease, and cannot be met by any method of reasoning. To propose the destruction of a beneficent industry growing out of the product of one of the most useful and wholesome gifts to man—the luscious, inspiring, health-giving grape—because, besides being food and health and joy to human beings, it was also converted into intoxicating drinks, seems the very ecstasy of perversity. The same kind of reasoning would uproot every orchard; it would bring sterility to our grain fields, and practically close every human mouth to bread.

It is admitted that mining for the precious metals—for gold and silver, which form the standard of value, and are of incalculable advantage to human society—is one of our greatest and most beneficent industries. Indeed, mining is the essential germ of California's wonderful growth. And yet there are people who would destroy it because of its relation to the stock exchange. Quite recently we read in a class paper, published in this city, a column of fierce fulmination against the practice of selling the shares of mining incorporations. The blow was aimed at mining as well. For the writer exclaimed that he would rather see wheat selling at \$2 a cental than to learn that a \$100,000,000 bonanza had been developed on the Comstock! There have been disgraceful transactions in mining shares in this city; the Chicago Grain Board is not without its low scandals; and the operations in railroad shares at the exchange in New York are a stench in the common nostril. What then? Shall mining and wheat growing and railroad building cease because of the dishonesty of some operators and brokers? Yet this is the logical result of the policy of the emotional economist. Every rational man knows that the stock exchange is not an unmixed evil. It has promoted mining enterprises and brought them to fruition, the successful prosecution of which was impossible without its aid and influence. So far as the integrity of the average stock-broker is concerned, we believe it will compare favorably with that of any other class of business men. Some time ago the *New York Nation*, which is the avowed and critical foe to every form of wrong, while speaking of the morals of the Wall Street brokers, bore cheerful testimony to their general fairness and honesty in transactions frequently involving millions of dollars. While daily exposed to tremendous temptations, the rule of practice was honesty and accuracy.

RALPH WALDO EMERSON.—Our distinguished countryman contemplates another, and, in his belief, final, visit to England next year. The London correspondent of the *Manchester Guardian* says Mr. Emerson has been moved to do this chiefly by what he has heard of the declining health of Mr. Carlyle, between whom and himself there has been, ever since they first met, the deepest sympathy and affection. Mr. Emerson is also anxious to make the acquaintance of several distinguished Englishmen, conspicuous among whom is Cardinal Newman, whom he characterizes as "the most religious man in England." As a proof of the growing favor of Mr. Emerson's writings, it may be mentioned that a well-known publishing house meditates the issue of a cheap edition of them, about which it will negotiate with Mr. Emerson on the occasion of his visit to London.

Registering the Cost of Mental Effort.

An apparatus, called the plethysmograph, by which mental effort, causing the expenditure of more or less blood, is measured, is one of the curious inventions of the day. Of course every word uttered by a speaker, every idea thought out by a writer, is attended by some physical loss, and, as has been remarked by an eminent naturalist, the speaker or writer "burns that others may have light." In one of Balzac's stories the hero becomes possessed of a magical wild ass's skin, which enables him to gratify all his wishes; but its surface represents the duration of the writer's life, and for every satisfied desire the skin shrinks in proportion to the intensity of the enjoyment, until at length life and the last vestige of the skin disappear with the gratification of a last wish.

Happily, our matter of life differs from the novelist's ass's skin in its capacity of being repaired and brought back to its full size after every exertion by rest and food and sleep. Any strain of the nerves or of the brain—like the labor of an editor or a lawyer, for instance—somehow takes blood. Dr. Holland has said that people who relished the interest of their morning paper little thought of the drain of blood which the printed sheet represented. But now, thanks to the tireless efforts of science, we may learn how much blood a thought, a strain or an emotion costs us.

This highly interesting announcement was made at Boston the other day by Prof. Barker, of Philadelphia, before the American Association for the Advancement of Science. The professor told his hearers that Dr. Mosso, of Turin, has measured the consumption of blood by the brain in its diverse mental acts. The arm of the subject to be operated upon is inclosed in a vessel tightly, the empty space being completely filled with water. If blood flows out of the arm to the brain, the vessel will hold more water; if the flow of blood is from the brain, water will flow out of the vessel; so that by a very simple apparatus we have a register of the demand of the brain for blood for any purpose. Here are some curious instances of the operation of the plethysmograph: Dr. Pagliani, whose arm was in the apparatus, was requested to multiply 267 by 8, mentally, and to make a sign when he had finished. The recorded curve showed very distinctly how much more blood the brain took to perform the operation. Hence the plethysmograph is capable of measuring the relative amount of mental power required by different persons to work out the same mental problem. Indeed, Mr. Gaskell suggests the use of this instrument in the examination-room, to find out, in addition to the amount of knowledge a man possesses, how much effort it causes him to produce any particular result of brain work. Dr. Mosso relates that while the apparatus was set up in his room at Turin, a classical man came in to see him. He looked very contemptuously upon it, and asked of what use it could be, saying that it couldn't do anybody any good. Dr. Mosso replied: "Well, now, I can tell you by that whether you can read Greek as easily as you can Latin." As the classicist would not believe it, his own arm was put into the apparatus, and he was given a Latin hook to read. A very slight sinking of the curve was the result. The Latin book was then taken away, and a Greek book was given him. This produced immediately a much deeper curve. Again, this apparatus is so sensitive as to be useful for ascertaining how much a person is dreaming. When Dr. Pagliani went to sleep in the apparatus, the effect upon the resulting curve was very marked indeed. He said afterward that he had been in a sound sleep, and remembered nothing of what passed in the room—that he had been absolutely unconscious; and yet every little movement in the room, such as the slamming of a door, the barking of a dog, were all marked on the curves. Sometimes he moved his lips, and gave other evidences that he was dreaming; they were all recorded on the curve, the amount of blood required for dreaming diminishing that in the extremities. The emotions, too, left a record.

IMPROVEMENT OF THE UPPER MISSOURI.—We learn from the *Helena Independent* of the 2d inst. that about 70 men are now employed by the Government in making improvements in the upper Missouri river, near Dauphan's Rapids, and it is informed that hereafter there will be little difficulty in navigating the stream until quite late in the fall. Boats have already transported to Benton about 9,000 tons of freight, and some 2,000 tons more will, it is hoped, be brought up the river before the season closes. This has proved so far an excellent season for freighting, and the river is two ft. higher than it was at the same time last year.

MILL MACHINERY FOR COLORADO.—It is stated that James R. Keene and other capitalists in New York, having purchased the Silver Cliff mine in Custer county, Col., contracted with eastern parties for the erection of a quartz mill. The mill failed to work the ore. The story goes that, instead of levying an assessment on the stockholders, Mr. Keene individually and at his own expense, contracted recently with a firm of this city for a mill to work 100 tons of ore per day, to replace the one of Eastern manufacture.

Rare Gold Quartz.

One day this week we saw a handsome collection of the richest gold-bearing quartz that we have seen for a long time. Indeed, several large pieces might properly be described as quartz-bearing gold, so greatly did the metal predominate over the mineral. In the collection, besides the rich specimens of quartz, there were fancifully shaped nuggets of fine gold, and others with little points of brilliant whitish quartz; there were coarse gold, gold dust, hammered gold and gold amalgam. Of the soft, malleable gold, which had been hammered out of the matrix and beaten flat, there was enough to fill a pint cup. The sight of this golden variety was sufficiently fascinating. This fine collection was brought to our office by Mr. W. W. Faher, who is the owner of the mine from which it was obtained. The mine is called the Faher, and is situated in El Dorado county, about four miles from Latrobe. The quartz occurs in a slate formation. The claim comprises two parallel veins about 20 ft. apart, and the veins vary in size from 6 inches to 2 ft. Both veins are opened by inclined shafts, the deepest of which is only 80 ft. In the deep incline, at a point some 50 ft. from the surface, occurs the nest or chimney from which the rich quartz and gold we have described were taken. In reply to our question as to the extent of the chimney, Mr. Faher said he had merely cut through a section of it, and that it lies there in mass at one side of the incline. Mr. Faher left at Wells, Fargo & Co.'s office, one mass of quartz, weighing 30 lbs., the surface of which is gold covered. He had with him one piece weighing 17 ounces, which contained 8 ounces of gold. The gold is of superior fineness, a mint certificate rating a lot of it at .935. The locality of the Faher is celebrated for the occurrence of the richest gold-bearing quartz. About a dozen years since a miner named Spawm took out of his claim in several days the splendid sum of \$25,000, and before he discontinued the work the mine had yielded \$100,000. This account was given by Mr. Faher, whose own experience in the neighborhood helps him to believe the story.

Insuring Miners' Lives.

The proposition to make the mine owners of Great Britain insure the lives of their miners is meeting with great opposition from the owners. This system is provided for by the "Employers' Liability Bill," and complaint is made that this is another straw to help break the camel's back. The effect of recent legislation has been to heavily tax mine owners, and this will be an additional burden. In some of the large collieries this would make an increase of expense of from \$15,000 to \$20,000 a year. The *London Mining Journal*, commenting on the proposition, says: "Why an employer should be so taxed, whilst the workman should become even less provident than he is at the present time, is not so logical a conclusion as might be expected from a judge expectant. Our leading men have long been endeavoring to inculcate habits of thrift upon the working classes, but the proposal of the Attorney-General is that of an entirely opposite course, for he would make employers do everything for their work-people without any counter-balancing advantages. Mine owners are now heavily handicapped, and to still further impose liabilities upon them, such as insuring the lives of those whom they employ, would simply be to cause serious loss of capital, and at the same time lessen the number of persons employed in mining operations."

It really seems that if there is to be an insurance it should be mutual, to say the least, where both masters and men should be interested in contributing towards it. Some such plan as that would be excellent.

THE NATIONAL PARK.—It appears that the natural wonders of the Yellowstone National park have made a strong impression upon Secretary Schurz, who recently, with Gen. Crook for a companion, made a horseback tour through the region. He has expressed great indignation at the depredations that are annually perpetrated there. In the park game is very abundant, and includes elk, deer, antelope, bears, and other animals; but the gamekeepers provided by the Government are insufficient to prevent the wholesale destruction of hunters, who are killing the animals merely for their skins. The entire unwholesome brood of curiosity hunters is also inflicting much injury by removing treasures which would have exceeding value to intelligent tourists. Around the geysers and other springs in the park there are many rare specimens of etalagmites and coralline depositions, which have required ages for their formation, all of which are liable to be injured or carried away by the vandals. The Secretary has expressed regret that proper action was not taken long ago for the preservation of the park, and it is his purpose to urge upon Congress the requisite legislation for the prevention of the depredations which are despoiling it of many of its beauties. We hope something efficient will be done at the earliest moment, for a further delay of five or ten years might work irreparable injury. Our forests are defaced and in course of destruction by the epilers. Let us make an earnest effort to keep their ruthless hands off of the National park.

Silkworm Culture in America.

The uniform failure of experiments in the culture of the silkworm in this country is the subject of an interesting article in a recent number of the New York Sun, the chief facts of which we present in the following summary. King James I of England made strenuous efforts to compel the planters of Virginia to grow mulberry trees and raise silkworms instead of tobacco, but always in vain. Under the Commonwealth no thought apparently was bestowed upon the pet project of James; and silk culture in the New World was left to its own attractiveness and promise of profit. It would not be possible to cite any other interest to which so much earnest effort has been devoted in this country with such an unbroken record of failure. Its victims were spread over a vast expanse of territory through a long course of years. In almost every case there had been just sufficient success attained to show that the conditions were favorable throughout the country for actual growing of the silkworm and their food. At the same time it was no less clearly shown that there was an insurmountable obstacle to the profitable prosecution of the business.

As early as the middle of the 17th century silk culture in Virginia was reported as "moderately thriving." Haudkerchiefs, dresses, waistcoats, and even a royal robe for Charles II were, it is said, made in the colonies of native grown silk. In 1732 the industry was started in Georgia, and 27 years later 10,000 lbs. of raw silk were shipped from Savannah to England, where it commanded a better price than any other. South Carolina commenced it about the same time, and in 1755 it was begun in Connecticut—the first mulberry plantation having been started on Long Island. In 1767 the delusion that silk growing was a good thing to do penetrated Pennsylvania, and a few years later to New Jersey, New York, and even to the New England States as far north as Maine. Everywhere the result was the same; the interesting experiment proved to be a financial failure. Yet people kept on struggling with it. In 1810 the three counties of Connecticut in which the industry was then most flourishing—that is, New London, Windham and Tolland—produced sewing and raw silk of the value of \$28,503, and fabrics from the refuse silk worth half as much more, and still it was a failure.

After a while State legislatures strove to encourage silk culture; Congress gave it favorable notice; the Secretary of the Treasury published a high book about it; men of wealth, theorists and experimenters mounted and rode it as a hobby; and finally the endeavors of speculative energy and misplaced ingenuity culminated in the memorable *morus multicaulis* mania of 1838-9. The frenzy was wide spread, and almost paralleled the tulip mania of Holland. Everybody was going to get rich in sericulture. Suddenly the bubble burst; thousands of persons were ruined; and the hueless of silk growing got a set-back from which it has never recovered. Still there are obstinate people scattered all over the country who try to carry on the business in defiance of the sharp lessons of experience. A devoted Frenchman in Kansas has sunk a fortune in it; thousands of dollars have been spent in the effort to force it in California; and in nearly every State there are small experiments going on constantly. Only a few days ago a large silk manufacturer in New England received a letter from a man out West saying that he had 3,000 cocoons for sale, and wanted to know how many cents each they were worth. They were worth to that manufacturer only a few cents a pound, and were not worth writing a letter for.

The one insurmountable obstacle in the way of profitable sericulture in this country, to which reference has been made, and one which it is scarcely to be hoped can ever cease to exist here, is the impossibility of procuring intelligent, skilled labor at prices such as are paid in China, Japan, Turkey, Italy and France.

The production of the cocoon is a very simple matter; but the utilization of it is a difficult and expensive one. In 1,000 ounces of cocoons there are only 150 ounces of pure silk, and of that quantity only 80 to 100 are fit for reeling. It is in that process of reeling that the value of the silk is established, for it is an exceedingly delicate, slow and painstaking art, on which depends the evenness of the thread, which is the great desideratum. The cocoons are thrown into warm gum, which makes their filaments adhere. If the water is too hot it partly dissolves the silk; if hard, it makes the silk liable to break. Six, eight or ten filaments, each as thin as a thread of an spider's web, are deftly unwound by the reeler from as many cocoons. The gum they bear causes them to adhere. The same number must be kept together all the time. When one breaks, or the available part of a cocoon is exhausted, another must be joined on so evenly that not even under a microscope is a roughness perceptible. The cocoons are never of the same size, their filaments varying from 1,300 to 3,000 yards in length, and the reeler must know just where to start and where to stop on each individual cocoon to turn out raw silk. And when he or she knows how to do all that, and is careful in doing it, and works faithfully, he or she may turn out one and a half or two lbs. of raw silk by a week's hard

labor, and, in doing so, will earn 15 or 20 cents per diem if working in France or Italy, half as much in Turkey, or one-third as much, or even less, in Japan or China.

It is no wonder, then, that a "filature"—the technical name for a filament unwinding establishment—cannot flourish in this country, where men and women capable of such work could not be got for less than \$1 per day. This labor must be not only skillful, but "dirt cheap" in order to be profitable. Nor will the cocoons, viewed as a crude crop, to be shipped abroad for reeling, pay for growing. That the results attained in this country have not been profitable, is clearly established by the fact that in 1876 it was computed that of 56,000,000 lbs. of silk, the product of all countries, only 16,000 lbs. were furnished by the United States, Mexico and Brazil together. And this is the result of 250 years of persistent endeavor to establish sericulture in this country. A business which requires such poorly paid labor to make it profitable is not adapted to the United States, and it seems like folly to attempt to force its growth.

VALUE OF THE DIAMOND DRILL.—Never, perhaps, in the history of the Comstock, has there been such extensive use of the diamond drill as within the past month. According to the Gold

General Albert J. Myer.

We present herewith an engraving of Gen. Albert J. Myer, Chief of the Signal Service Bureau, who died on the 24th ult. at Buffalo. Gen. Myer was known all over the country, although very few knew his face. He was better known as "Old Probabilities," a familiar cognomen applied to the official representative of the Signal Bureau. This distinguished officer was born at Newburg, in the State of New York, in 1828. He graduated at Hobart College, at Geneva, in that State, in 1847. After applying himself to the study of medicine, he took the degree of M. D. at the University of Buffalo in 1851; and in 1854 he was appointed Assistant Surgeon in the United States army. He served in the medical department until the breaking out of the civil war, when he was appointed Chief Signal officer. He continued in the service until the close of the war, and received the brevet rank of Lieutenant-Colonel, Colonel and Brigadier-General of Volunteers. In 1866 Gen. Myer was placed at the head of the Signal Service of the regular Army, and in 1870 he was charged with the taking of meteorological observations at the military posts and other points in the country. It was

THE LATE GEN. ALBERT J. MEYER, CHIEF OF THE SIGNAL SERVICE BUREAU.

Hill News, the lower levels of the Ophir and the Mexican have been thoroughly perforated, both east and west, by which means, it was informed by Supt. Patton, he had been enabled to discover the exact location of the water courses which flow through the formations along the lode. This was the chief value of the diamond drill. For example; it was of great importance sometimes to drill ahead when running drifts, and ascertain what danger existed of an influx of water. Floods in the mines were thus frequently avoided. Mr. Patton fortified his statement by citing the case of the Savage, where the inflow of hot water from the north drift of the 2200 level flooded that mine and the Hale & Norcross for four years. Had the body been first tapped by the diamond drill, that disastrous flood would have been avoided. Besides its great value in detecting the presence of water, the diamond drill has a certain use as a prospector. It is true it is not always trustworthy when a body or a streak of ore has been found, especially if the ore is soft. If a vein of chloride ore, narrow and soft and rich, is struck by the diamond drill, it will feed the boring for some distance, and so mislead by giving indications of a large body of milling ore. Still it is often useful in determining whether there is any ore in a given region worth drifting for. A new use of the diamond drill has recently been made in the Jacket and Overman, in which mines it has been sent down perpendicularly, to guard against water.

THE NOTORIOUS EMMA MINE.—This notorious mine, which has alike dissipated fortunes and reputations, is likely, according to the Salt Lake Tribune, to resume its old place among the rich mines of Utah Territory. The mine is now in better condition and fuller of promise than it has been at any time since the wrangling and counter-fighting over it first began.

largely owing to Gen. Myer's executive ability, scientific knowledge and capacity for mastering details that the Signal Service of the United States has succeeded in reaching its present condition of usefulness.

ELECTRIC LIGHTS IN A QUARTZ MILL.—We are informed by the Salt Lake Tribune of the 12th inst. that the Walker Bros. of that city have just entered into a contract with the agent of the Brush electric light for one of the largest-sized machines with 14 lights, with which they will illuminate their quartz mill at Walkerville, Montana. These lights will be disposed about the works as follows: seven will be used in the large mill, four in the small one, one in the hoisting works, and two will be placed so as to light the dumps. The illumination afforded by this number of lights will enable the men to work at night as well as in the daytime, while the expense will be less than that of ordinary light. It will be the first instance of the employment of the electric light in Montana.

STRIKES IN UTAH MINES.—During the past week, according to the Salt Lake Tribune of the 12th Sept., several highly important developments of ore have been made in the Bingham district, Salt Lake county. The strike of sulphuret ore in the Lucky Boy, in Black Jack gulch, is pronounced to be very interesting, and is likened to some of the Comstock ore. A short time before a similar class of ore was struck in the Northern Chief. In the Summit mine they have uncovered some remarkably fine carbonate ore; and in the Stewart No. 2 they have struck a good body of carbonate ore high in silver. The Prince of Wales Con. has completed the connection between tunnel and shaft, and a body of ore two ft. wide extends the entire distance.

No hope is entertained for the men in the mine at Seaham, England.

The Photophone—Sound Reproduced by Light.

"There is nothing new under the sun," said the wise man. The times have changed. Now everything is new, and novelty follows novelty. The growth of natural knowledge has broadened the field of investigation, and increased the number of trained specialists, and an answer to any special inquiry is almost certain to come from some part of the scientific domain. The latest thing—it is simply a marvel—in applied science is the discovery that "sounds can be produced by the action of a variable light from substances of all kinds when in the form of their diaphragms." In other words, the ray of light is substituted for the connecting wire, and sounds produced at one station are reproduced at another. It is well known that the action of the telephone is due to variations in an electric current, caused by a diaphragm set in vibration by the voice, the current thus modified reproducing its vibration on a sensitive diaphragm at the other end of the circuit. In the photophone, as the new instrument is called, the changes in the electric current are made during its passage through the metal selenium. This curious metal was discovered by Berzelius in 1817, and by him named selenium. It is not known to occur native, although several native compounds of it are known. In its modifications it is both a conductor and a non-conductor of electricity. A steady light allows a current to pass through an even resistance; a varying light varies the resistance; so that the current is stronger or weaker after passing through the selenium, and in a telephone its vibrations are easily turned into vibrations of sound. The inventors have already conversed between points about 600 ft. apart, and they believe that a similar result can be obtained as far as a beam of light can be flashed. The simplest apparatus yet devised consists of a plane mirror of flexible material—such as silvered microscope glass or mica—which will quiver with the vibrations of sound. On this surface is collected through a lens a beam of light from any source, good success having been obtained from a kerosene or candle flame. The parallel beam reflected from the plane mirror is thrown to a distant concave mirror and focused on a piece of selenium, electrically connected with a telephone. The voice throws the plane mirror into vibrations, which modify in intensity the ray of light, which rapidly changes the resistance of the distant selenium, thus varying the electric current in the telephone as the voice now does directly. Another means of affecting the beam of light is by a disk, perforated with elits, which is rapidly turned, producing in the selenium a continuous musical tone, whose pitch varies with the rapidity of the disk's rotation, a silent motion thus producing a sound. A strange thing is that some substances placed in the beam of light do not cut off the sound. A sheet of hard rubber, for instance, made the beam invisible, but the musical note was still heard. Other experiments suggest the possibility of doing entirely without the electric current in the telephone at the receiving station. Many other substances were substituted for selenium, the affected ray of light focused upon them, and the musical note was heard without the aid of a telephone or battery. Only carbon and thin glass failed to give a sound.

Some minor details of the difficulties encountered and overcome in using selenium in the apparatus for speaking from a distance, are of interest. A small bar of selenium has a resistance to electricity equivalent to that offered by a telegraph wire long enough to reach from the earth to the sun. Even the cold light of the moon lessens this resistance, and such a brilliant light as that of burning magnesium wire halves it. But Ball and Sumner had to work long to reduce this resistance within manageable limits. No selenium crystal was ever known to measure less than 250,000 ohms of resistance in the dark. They have made cells measuring only 300 ohms in the dark and 155 ohms in the light, by melting selenium to brass conductors, a chemical union being formed which lessens the resistance at the point of contact of the two substances. Their 50 forms of apparatus are based on one of two principles—either to control the source of light, or to modify the beam itself, the second being the most practical.

The inventors of the photophone are Prof. Alexander Graham Bell, the acknowledged inventor of the telephone, and Mr. Sumner Tainter, of Watertown, Mass. The paper describing this invention was read by Prof. Bell before the American Association for the Advancement of Science, and was illustrated by diagrams projected on a screen, and by working apparatus. The interesting paper is described as a model of precise statement and scientific accuracy.

The latest excitement in the quartz line in Sierra county is the striking of some very rich quartz in the Forest Queen mine, near the mouth of Slug canyon, Downieville. About a week ago a small seam was struck, and in running some five ft. the ledge widened out to nearly four ft. wide. Several tests made lately ranged from \$20 to \$100 per ton.

STATE ENGINEER HALL returned to Sacramento lately from a visit to the scene of the debris work on the Yuba and Bear rivers. He reports the work as progressively finely.

[From Vera Cruz to Mexico.

After an absence of 22 years I revisited Vera Cruz. This little oriental city, hid away at the farther end of the Gulf of Mexico, is, in itself, not unattractive. Oriental I call it, for it is of Moorish descent, and its lineage is visible in its cupolas of white, rose-color and blue, overtopped here and there by Christian spires; in its houses painted bright red, yellow or blue; in its flat terraces, with their pyramidal ornaments. Cities are more enduring than men, and Vera Cruz has become young again, with its dwellings newly painted, its white bell-towers, its enameled cupolas, its new houses and monuments. There is a holiday air about it, and a faint Haussmann breeze has come across the Atlantic. The plaza, which, when I last saw it, was paved with angular stones, covered with filth and cut up with muddy brooks, is now a delightful square, planted with palms and other trees, robed in verdure, and paved with marble. In the middle we see a handsome fountain, while all around it are fine *cafes*, stores, the cathedral, the municipal palace, and other structures that vie with one another in giving it a fit surrounding. In the daytime the air is cool in the plaza; in the evening long lines of promenaders and of pretty Mexican ladies fill the walks. It is like one vast greenhouse.

The train left at 11:30 P. M., and during the night we traversed one of the most picturesque portions of the route. At daybreak we reached the plateau of Orizaba, and the prospect was delightful. On all sides rose mountains tinged with the brightest colors by the rising sun. The volcano of Orizaba commanded them all with its snowy cone. We sped through coffee plantations and vast fields of tobacco and bananas. We crossed ravines over venturesome iron bridges, meeting a fresh surprise at every turn.

From Orizaba we ascended by an easy grade to Maltrata, and then the train drawn by two engines made ready to mount the famous Cumbres de Aculzingo. We were now in the temperate, we were soon to be in the cold zone. The route lies before us describing long *detours* and ascending heavy grades; our two locomotives, puffing and howling, and as it were exhausted, make their way amid the grandest scenery. In three hours we reach the plateau of the *tierra fria*.

In these three hours we made an ascent of 4,810 ft., that being the difference of elevation between Orizaba, which is 4,810 ft. above sea-level, and Esperanza, which is 9,620 ft. At the latter place we dined. Our route now lay over vast dusty plains like Arabian deserts. The *haciendas* were few and far between, while the stunted maize and the poor, sparse crops of wheat were evidence of the dryness of the soil. The region is deplorably bare of vegetation, but the bold lines of the mountains defining the horizon, the vastness of the plain, the peaks which here and there break its monotony, the dust-whirls seen rising on every side, give it a strange aspect, and impress upon it the character of stern desolation.

But the railway has changed the face of this plateau. We might almost say that here the railway is a foreign intruder (*s'y trouve depaysee*); and it more than any other cause has made the region a solitude. We see no more the long convoys of mules that used to wind their way from Vera Cruz to Mexico, the lumbering wagons, the *arrieros* in picturesque costumes; no longer do we hear the silver bells of the *madrinas* (bell-mares). The little huts along the roadside where the muleteers were wont to quench their thirst, and the great *corales*, or yards, in which the mules were shut up at night, have disappeared.

The railroad stretches toward the northwest, and after passing Huamantla skirts the volcano of La Malinche, leaves Puebla about 20 leagues on the left, then passing through Apizaco it enters the Llanos of Apam. There we are in the land of *pulque*, the headquarters for the production of the wine of Mexico. On all sides are plantations of maguey (agave), and at every station are wagons unloading casks of the liquor so much liked by the Indians. This not very inviting looking beverage in color resembles a strong decoction of orgeat and water. It is thick, viscid, stringy, and has a rather strong taste of leather. It is said to be wholesome, and one becomes accustomed to it. It is consumed in enormous quantities in Mexico.

We next come to La Palma and then to Otumba, famous for the victory won by Cortes. Finally, leaving on the right the pyramids of San Juan de Teotihuacan, we arrive in the capital.

Mexico has undergone a greater change even than Vera Cruz. The Grand plaza, which formerly was bare of vegetation, is now a fine park with eucalyptus trees 100 ft. in height, though planted hardly 12 years ago. Handsome houses, showing novel architectural forms, have sprung up everywhere; new quarters now occupy the place of demolished convents; pretty squares surprise the returning traveler at street crossings, and the magnificent promenade constructed by Maximilian, and which is to be extended as far as Chapultepec, would do honor to the proudest capital.

So, too, the toilets of the ladies and the costumes of the gentlemen are changed for the better, and are now more costly, perhaps, but they have lost in picturesqueness the nearer they have approached the fashions of Europe.—*M. Charnay, in North American Review.*

An iron church was sent from London for the Esquimaux in 1877, and after being two years on the way was erected last October. Eight Esquimaux have recently been baptized in it.

INCERSOLL ECLIPSE ROCK DRILLS.

The Most Economical Air Compressors in the Market.

MINERS' HORSE-POWER.

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The Power is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending the bucket. The frame of the Power is hoisted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX,
49 Fremont St., S. F.

INCERSOLL Rock Drill and Air Compressor.

The undersigned having been appointed sole agent for the Pacific coast, will keep always on hand a large stock of the various sizes, together with duplicate parts, all of which he will sell at factory prices. The Incersoll is the only Rock Drill now in use on the Comstock.

GEO. R. FOARD, GEN'L AGENT,
No. 18, First St., S. F.

ST. DAVID'S.

A FIRST-CLASS LODGING HOUSE
CONTAINS 113 ROOMS.
715 Howard St., near Third, San Francisco.

This House is especially designed as a comfortable home for gentlemen and ladies visiting the city from the interior. No dark rooms, Gas and running water in each room. The floors are covered with body Brussels carpet, and all of the furniture is made of solid black walnut. Each bed has a spring mattress, with an additional hair top mattress, making them the most luxurious and healthy beds in the world. Ladies wishing to cook for themselves or families, are allowed the free use of a large public kitchen and dining room, with dishes. Servants wash the dishes and keep up a constant fire from 6 A. M. to 7 P. M. Hot and cold baths, a large parlour and reading room, containing a Grand Piano—all free to guests. Price single rooms per night, 50 cts.; per week, from \$2.50 upwards.

R. HUGHES, Proprietor.

At Market Street Ferry, take Omnibus line of street cars to corner Third and Howard.

AMERICAN MACHINE AND MODEL WORKS.

Experimental and Fine Special Machinery, Planing, Gear Cutting, Patterns, Models for Inventors, etc. Printing Press and General Machine Repairing. Punches, Dies, Taps, Reamers, etc., made and repaired.

I. A. HEALD, Proprietor.

514 Commercial Street, above Sansome, San Francisco.

California Inventors

Should consult DEWEY & CO., AMERICAN AND FOREIGN PATENT SOLICITORS, for obtaining Patents and Caveats. Established in 1860. Their long experience as journalists and large practice as patent attorneys enables them to offer Pacific Coast inventors far better service than they can obtain elsewhere. Send for free circulars of information. Office of the MINING AND SCIENTIFIC PRESS AND PACIFIC RURAL PRESS, No. 202 Sansome St., San Francisco.

MINING ENGINEER,
Room 75, 115 Broadway, New York.

Agent for PADDOCK'S Ore Dressing Machinery.
Mining Machinery supplied.

San Francisco Cordage Factory.

Established 1856.
Constantly on hand a full assortment of Manila Rope, Sisal Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.
Extra sizes and lengths made to order on short notice.
TUBBS & CO.,
611 and 613 Front Street, San Francisco

Pumping Engine For Sale.

NEW UPRIGHT WILCOX ENGINE.

16-inch Cylinder, 6-inch Stroke. About 8-Horse Power. Will raise 3,000 gallons per hour. Was used to dig the well at Chronicle office. Never used otherwise, and is in perfect order.

PRICE, \$300.

Mr. Wilcox sold similar engines at \$300 each. I have taken this engine as an attorney fee, and will sell it for this price and WARRANT it. Address

MANUEL EYRE,
Law Office, No. 636 Clay St., room 25, S. F.

LAND

Good land that will raise a crop every year. Over 14,000 acres for sale in lots to suit. Climate healthy. No drouths, had floods, nor malaria. Wood and water convenient. U. S. Title, perfect. Send stamp for illustrated circular, to EDWARD FRISBIE, Proprietor of Reading Ranch, Anderson, Shasta County, Cal.

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street, San Francisco, Cal.

LEFFEL'S IMPROVED WATER WHEEL.

PRICES REDUCED!

PATENTS REISSUED 1868.

The "OLD RELIABLE" with improvements, making it

THE MOST PERFECT TURBINE NOW IN USE

Comprising the Largest and the Smallest Wheels, under both the Highest and Lowest head used in this country. Our new Illustrated Book sent free to those owning water power.

Those improving water power should not fail to write us for New Prices, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

JAMES LEFFEL & CO., Springfield, Ohio,
and 110 Liberty St., N. Y. City.

Gardner Governors.

These Governors have long been known as the BEST STEAM GOVERNORS made, and as lately improved and perfected, they have no rival.

Over 13,000 of Them in Use.

They are sold at the same price as ordinary Governors, and the SAFETY STOP alone is worth double the price of any other Governor. Send for circular.

BERRY & PLACE MACHINERY CO.,
323 & 325 Market St., San Francisco.

Metallurgy and Ores.

Nevada Metallurgical Works,

No. 23 STEVENSON STREET,
Near First and Market Streets.

Ores worked by any process.
Ores sampled.

ASSAYING in all its branches.

Analysis of Ores, Minerals, Waters, etc.

WORKING TESTS MADE.

Plans furnished for the most suitable process or working Ores.

Special attention paid to Examinations of Mines; plans and reports furnished.

E. HUNN,
O. A. LUCKHARDT,
Mining Engineers and Metallurgists

JOHN TAYLOR & CO.,

Importers of and Dealers in

ASSAYERS' MATERIALS.

Mine and Mill Supplies,

CHEMICAL APPARATUS AND CHEMICALS, DRUG-
GISTS' GLASSWARE AND SUNDRIES, Etc.

118 and 120 Market Street, and 15 and 17
California St., San Francisco.

We would call the special attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our stock of Clay Crucibles, Mullers, Dry Cups, etc., manufactured by the Patent Plumbago Crucible Co., of London, England, for which we have been made Sole Agents for the Pacific Coast. Circulars with prices will be sent upon application.

Also, to our large and well adapted stock of

Assayers' Materials & Chemical Apparatus,

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.

Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application.

JOHN TAYLOR & CO.

W. BRUCKNER'S

ROASTING FURNACE

AND

Ore Pulverizers.

(Awarded the Premium Gold Medal at Naples, Italy.)

The furnace is especially adapted for roasting rebellious ores; there are more than fifty in use in Colorado, giving perfect satisfaction.

The Ore Pulverizer is built in different sizes. It is preferable to Stamp Mills because it requires less power and less repairs than Stamps. No extra expense for setting up, and no foundation. Less weight and less cost than stamps.

Furnished also in sections for packing.

For circulars and prices apply to

Machinery.

GOLD AND SILVER

Grinding and Amalgamating MACHINERY.

* Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.

SPERRY'S Wrought-Iron Frame FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular. We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc., Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, suitable for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

\$2,550.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

MOREY & SPERRY,

No. 145 Broadway, - NEW YORK.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

NOW READY!

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW on SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Quarto. 234 Illustrations.

By ROBERT GRIMSHAW, Ph. D., M. E.,

Member of the Jury on Wood-working Machinery at Paris Exposition of 1878.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw artistically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand saws, Mulley, jig, drag, circular, cylinder and hand saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, sawing, gumming, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 36 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copiously indexed.

Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the price in this date made \$2.50, postage paid.

ROBERT GRIMSHAW,

624, 626 and 628 Market Street, Philadelphia

March 10 1880.

A Card from Architects.

The California Architect and Building Review.

Office, No. 240 Montgomery Street, San Francisco, Cal.

It is with pleasure that we publish the following from

Prominent Architects in this city: Believing that a journal of the kind is a necessity on this coast, and judging from what has appeared in the "Quarterly Architectural Review," we are led to believe that the CALIFORNIA ARCHITECT AND BUILDING REVIEW

will be worthy of generous support and encouragement. We therefore pledge our cordial sympathies, personally, and hope that the enterprise will receive kindly recognition and liberal support from all Architects and Builders and the public generally. (Signed) David Farquharson, Wright & Sanders, S. E. Williams, Thos. J. Welsh, P. Huerta, John Marquis, H. McDougal & Son, Wm. Mosser, Wm. Curlett, Meeker & Banks, W. G. Hoagland, S. & J. Newsom, B. Hendrickson

METALLURGICAL WORKS,

STRONG & CO., 10 Stevenson Street, S. F.
ORES SAMPLED, TESTED, ASSAYED.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1887.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also contains throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore. It contains 155 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3.00 coin, postage free.

Books for Miners and Millmen.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arsenurets, and gold and silver ores generally, with 120 lithographic diagrams. 1887. This work is unequalled by any other published embracing the subjects treated. Post-paid, \$7.50. Printed and sold by Dewey & Co., S. F.

AARON'S TREATISE ON WORKING SILVER ORES.—Illustrated. 114 pages. 1878. A useful and practical work, free from technicalities and extremely serviceable for miners' use. Post-paid, \$2. Published and sold by Dewey & Co., S. F.

COPP'S HANDBOOK OF MINING LAWS.—Containing the U. S. Mining Laws, Digest of Decisions, Forms, etc., 1877. Pocket size, and very handy and convenient for miners. Post-paid, \$1.00. Sold by Dewey & Co., S. F.

A New Edition.

KUSTEL'S ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. Illustrated. 156 pages. 1880. A valuable and carefully written work. Postpaid, \$3.00. Sold by Dewey & Co., S. F.

COPP'S AMERICAN SETTLERS' GUIDE.

Public Land System Explained; How to tell Township and Section Corners; How to Homestead and Pre-empt land; How to Enter land under Timber Culture, Desert, Townsite and other Laws. Sent by mail postpaid for 60 cents.

DEWEY & CO.,

202 Sansome St., S. F.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.]

FOR THE WEEK ENDING SEPTEMBER 7th, 1880.

231,900.—BENCH-PLANE.—A. P. J. Bossel, Virginia, Nev.
231,857.—SUBMARINE WALL.—D. A. Dyer, Ferndale, Cal.
232,044.—BUTTON.—L. Leszynsky, S. F.
231,907.—VALVE.—G. Milne and W. H. Gants, S. F.
232,056.—PICK.—C. Norton, Tuscara, Nev.
231,908.—FORMING DRAIN PIPE.—W. Hamlet, Merced, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast inventors transacted with perfect security and in the shortest possible time.

Recent Decisions Relating to Patents, etc.

We give below brief abstracts of decisions rendered upon patent cases in litigation, for the benefit of our readers:

DECISIONS OF THE U. S. COURTS.

Brickell, et. al. vs. The City of New York.

U. S. Circuit Court, Southern District of New York. Decided October Term, 1879; Wheeler, J.
1. Letters Patent, No. 31,132, granted August 13, 1868, to Wm. A. Brickell, for an improvement in feed-water heaters for steam fire engines, construed and sustained.

2. Section 7 of the Act of 1880, which provides that every person or corporation may use and vend to others to be used, any specific machine, manufacture, or composition of matter which they have purchased, or constructed prior to the application for a patent, applies in cases of patents for substantive things to the particular things, so purchased or constructed only, and does not include the right to practice the invention without liability.

3. The patent involved in the case of McClurg vs. Kingsland, was for a method of casting iron rollers, and it is not probable that the decision rendered in that case would be followed beyond cases of the same statutory class.

4. By the Act of 1870, the right of a person constructing or purchasing a patentable article before the application for a patent is limited to the right to use or vend the specific thing, and this, whether it is regarded as a legislative construction of the former Act or not, may properly govern the right of recovery in actions brought since its passage.

5. For an infringement of a patent by its fire department, a city is liable.

Washburn and Moen Manufacturing Co. vs. Haish.—Barbed Fence Wire.

U. S. Circuit Court, Northern District of Illinois. Decided October 14, 1879. Blodgett, J.:

1. A person has no right to mark his goods with any words or terms indicating that they are manufactured under a patent which he does not own, and has no right to use.

2. A defendant, having so marked his goods, will not be allowed to defend himself by denying the validity of such patent.

An injunction will be issued restraining defendant, his agents, attorneys, servants and associates, from marking any barbed fence wire or packages of barbed fence wire, with any words or letters indicating that said wire is manufactured, either in whole or part, under, or pursuant to re-issued patent, No. 6,902.

Burton vs. The Town of Greenville.

U. S. Circuit Court, District of New Hampshire. Lowell, J.:

1. Letters Patent No. 10,497 granted to Geo. D. Burton, February 19, 1873, for a design for a street lamp declared invalid.

2. A design patent is invalid if the device embraced thereby was in public use or on sale more than two years before the date of the filing of the application on which such patent was granted.

St. Louis Stamping Co. vs. Quinby, et. al.

U. S. Circuit Court, Eastern District of Missouri. Decided March 16, 1880; Treat, J.:

If a few persons form themselves into a corporation under the Missouri Statutes, the business of which is the necessary infringement of a patent, they cannot escape individual liability for the acts done in the corporate name.

Statement of the case: The defendants were stockholders of a corporation. The infringement consisted in making and selling an article of manufacture. The complainant contended it was entitled to recover as damages; the defendants having made no profit, the profits it would have made on the articles sold by the defendant, and offered no other proof as to damages. It also contended that the defendants were liable jointly and severally for such damages. The master, in his report, negatived both of these propositions, to which action exception was taken.

* More complete reports of the proceedings may be found on file in the office of the MINING AND SCIENTIFIC PRESS Patent Agency, 202 Sansome street, S. F.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

MAGAZINE FIRE-ARM.—George E. Williams, S. F. Patented Aug. 31, 1880. No. 231,390. The improvements shown in this fire-arm are more especially applicable to that class of guns in which the cartridge is received from the magazine into a carrier-block, and is elevated by this block to a level with the bore of the gun, and is then forced into its chamber in the barrel by a carrier-holt or breech-pin operated by a lever and suitable connecting-link or arms. This invention consists of a peculiarly slotted plate, formed with the breech-pin holt, and adapted to reciprocate the holt by the action of the guard lever. It also consists, in combination with the holt, of a hinged locking-block, which is connected with the guard-lever by links, and is thrown up by them to allow the holt to be retracted, and is drawn down so as to lock it firmly when it has been forced forward and the cartridges introduced to its chamber ready for firing.

HOISTING MACHINE BRAKE.—William R. Eckart and Hans C. Bahr, S. F. Patented, Aug. 31, 1880. No. 331,766. This invention relates to certain improvements in that class of machinery which is used for hoisting and lowering in mines and other places, but which is more especially adapted for heavy mining work; and it consists in a novel construction and operation of the friction brakes, by which the speed of the descending load is regulated, checked or stopped at will, said brakes being adapted to move on parallel lines, so that all parts of the faces of the brake-shoes will be approached to or retracted from the drum at an equal rate of speed.

BUTTON.—Lester Leszynsky, S. F. Patented Sept. 7, 1880. No. 232,044. This invention relates to an improvement in buttons and similar devices which are used for connecting portions of clothing or other articles together; and it consists of a stem, having two parts projecting from the button or head, in combination with a rubber or other elastic center, which is held between the button and the goods, and furnishes an elastic, non-wearing surface, which the button-hole surrounds.

PICK.—Corbin Norton, Tuscara, Nev. Patented Sept. 7, 1880. No. 232,056. This pick is especially useful for miners' purposes where the tools receive hard usage. The improvements consist in forming a head of malleable iron, cast with a socket for the pick-handle, and having a slot through which the pick itself is passed, the pick being secured in place by a key fitting into a central notch. No wedging of the handle is necessary to keep it in place, and neither pick nor handle is apt to get loose from the head.

STEAM BOILER.—John B. Ward, S. F. Patented Aug. 31, 1880. No. 231,874. This invention consists in certain details of construction, whereby perfect circulation of the water in the boiler is accomplished by the water being drawn from the colder portions of the boiler to that where greater heat is obtained. It also relates to a peculiar means by which the steam is dried and superheated while in the boiler so that the cylinder of the engine will receive dry steam direct from the boiler at each stroke of the piston.

PROCESS FOR PRESERVING MEAT IN THE CIRCASS.—Richard Jones, Berkeley, Gloucestershire, England. Patented, Aug. 31, 1880. No. 231,807. This process consists in utilizing the circulatory organs of the blood to equally distribute throughout the body a solution, and by this action to mingle the substances intimately with the blood, so that they permeate the whole body and coagulate with the blood in every part, and thoroughly preserve the meat without giving it a sodden appearance.

SCRAPER.—Assaria Rewrick and John D. Gilmore, S. F. Patented, Aug. 31, 1880. No. 231,850. The scraper is formed in a cup-shaped triangular form. It is made by means of a die in which it is struck up, in such a form as to give the greatest strength with a minimum of metal. By this construction the scraper can be kept sharp with but little grinding.

AFRICAN EXPLORERS KILLED.—Long before its exploration shall be achieved, Africa is likely to prove the graveyard of many of the most enterprising and brave men of the times. The London Standard, in commenting upon the sad news which had been received at Zanzibar of the murder of Capt. Carter and Mr. Cadenhead, remarks that it adds two more victims to the long list of those who have sacrificed their lives in the interest of African exploration. Hitherto disease and not violence has been the cause of the fatality which has overtaken so many of the explorers of the dark continent. From the facts which have reached us it would, however, appear that the gallant pioneers whose loss we have to deplore met their death at the hands of a chief named Wrambo. But, as the expedition which they commanded was, at the latest date, in the country of a roher king called Mercambo, not far from Lake Tanganyika, the name has, in all probability, been altered in telegraphing. Messrs. Carter and Cadenhead, though Englishmen, were employed under the auspices of the Belgian branch of the International Society for the exploration of Africa. The leading object of the expedition sent out under its auspices is not so much geographical discovery as the establishment of centers of civilizing influence and commerce at various points of the interior. The first of these stations was founded in August, 1879, by M. Cambier at Karama, on the eastern shore of Lake Tanganyika, 140 miles south of Ujiji. In December M. Cambier was joined by Messrs. Popelin and Carter with the Indian elephants, of which only one remained. Another reinforcement, constituting the fourth expedition, under Messrs. Burdo, Rogers and Cadenhead, was far on its way when last heard of, and was sanguine of soon communicating with Mr. Stanley. The latter, by the aid of steam launches, is endeavoring to ascend the Congo, which, amid so many perils, he descended three years ago. The introduction of elephants into African exploration was a great step in advance, and it was fondly believed that one of the chief difficulties in the path of travel had at last been overcome.

Tricks of Charlatany.

Some people seem inclined to break from the well-beaten paths of experience, which are illuminated by the steady light of science, and to grope about in the labyrinths of alchemy. It would appear that a modern Midas has just startled many of the good people of Calistoga from their propriety. A dispatch from there says that a man named Tichenor had that day in the "presence" of many of our citizens extracted the sum of \$14.35 in gold from a 5-gallon pail of water from a mineral spring in this neighborhood. Of course Midas Tichenor knew how the gold got into the water; but that is his "patented secret," and is only to be had for coined money. The extraction of the gold was the least difficulty of the prestidigitator; but it takes gold in some form to salt even spring water. After this last brilliant success we would suggest that the Calistoga Midas try his hand on—let us say, as giving the least promise of being gold-bearing—a common doughnut. We believe the other myth fits the case of this Midas, and that he would better don his Phrygian cap.

Since the above was written Mr. Henry G. Hanks, State Mineralogist, has visited the scene of Mr. Tichenor's operations, and proved the whole thing a humbug. In conversation with Mr. Hanks he stated to the writer that he should have paid no attention to the matter had he not received letters from the East and inquiries from here, relative to the "golden water." When he became convinced that people were really thinking of investing he went to Calistoga. He took demijohns and filled them with this alleged gold-bearing water and sent them to the city. He then interviewed Mr. Tichenor, that gentleman being reluctant to divulge his "secret," giving as a reason that he had not secured his patent and did not want to lose "his rights." He tried to exact a promise from Mr. Hanks that he would not divulge what he saw, a request very properly refused. With reluctance he proceeded to show how he got the gold out in the presence of Mr. Hanks and several others. Among other things he took a bottle from a closet, and poured in a couple of ounces of what Mr. Hanks supposed was chloride of gold. Mr. Hanks asked to see the bottle, as this reaction which took place in the liquid assured him that chloride of gold had been introduced. Mr. Tichenor refused to allow him to see the bottle or its contents, whereupon Mr. Hanks told him that he was using chloride of gold, and that his "process" was a humbug, or words to that effect.

On his return to this city Mr. Hanks made a careful analysis of the mineral water, although convinced there was no gold in it, and the analysis bore out his convictions.

Tahoe—Origin and Meaning of the Term

EDITORS PRESS:—Prof. John LeConte, in his article on the "Lakes of the Sierra Nevada," published in the Press of the 11th inst., in speaking of the origin and meaning of the name now borne by Lake Tahoe, remarks that it is supposed to be of Indian derivation, and to signify, in the Washoe dialect, "big water," or, according to other interpretations, "deep water," etc. In this supposition Prof. LeConte is correct, as the following facts tend to show: Visiting the "eastern slope" in the summer of 1859, I employed one of the head men of the Washoe tribe to accompany me on a visit to this sheet of water, then known as Lake Bigler—a name given to it, I think, a short time before by a party sent out during the gubernatorial administration of John Bigler to survey a wagon route over the Sierra Nevada. Inquiring of my guide the Indian name for this water, he told me that they called it "Tah-hoe-ee," meaning big lake or water.

In some remarks on that section of country published at the time, but in what paper I cannot now recollect, I made mention of this fact, which then, no doubt, for the first time appeared in print, and thus attained to general publicity. How and why the term came afterwards to be adopted, superseding the several names by which the lake had previously been known, is in the above article sufficiently accounted for by Prof. LeConte.

The foregoing is the correct and only meaning of the word in the Washoe language, and the above is a true version of the time and manner in which it came to be applied to this lake. As used by the Washoe it is a word of three syllables, with the chief accent on the last, as set forth above; and since it is likely to be retained in our geographical vocabulary, I suggest that we adopt this pronunciation, as being more analogous to the Indian tongue and likely to work a uniformity in the popular method of pronunciation, which now vibrates between "Tay-hoe," "Tah-hoe" and "Ta-hoe."

HENRY DEGROOT.

Discovery of a Submarine Plateau.

The officers of the Coast Survey announce the discovery of a submarine plateau under the Gulf stream off Charleston. The existence of this plateau has not been thought of; and yet it must exert an important influence on the Gulf stream temperature as well as on the climate of our southern seaboard.

In running a line of deep-sea dredgings off Charleston, Commander Bartlett was recently surprised to find in the axis of the great stream depths of from 233 to 450 fathoms only, where it was thought they would range from 600 to 1,000 fathoms. This "swell of land" rising from the Atlantic bottom was found stretching eastward 150 miles between the parallels of 32 and 32½ degrees, at the northeastern terminus of which the depth of water suddenly increased from about 450 to 1,386 fathoms.

The submerged ridge projecting from the Carolina coast must obviously serve as a fender or bar to deflect from our southern seaboard the underflow of arctic water coming from Newfoundland, and by forcing the glacial stream far to the eastward, it thus allows the great "river in the sea" to retain its tropical heat, unreduced by commixture with the polar undercurrent, all the way from the Gulf to Charleston. This inference from the recent coast survey soundings is confirmed by the temperatures of the Gulf stream on the Admiralty chart, which shows a decided cooling of the stream after it passes north of Charleston, and also, what is more remarkable, that in September (when the ocean is at its warmest) the stream is warmer between Charleston and the Florida channel than it is even in the Gulf itself. The peculiar topography of the Atlantic bottom off the Carolina coast, it would seem, explains also the fact, which has lately excited much surprise, that the immense June flow of ice-bearing water from Newfoundland made no impression on the temperature of the southern seaboard. The summer of 1875, like that of 1880, opened with an exceptionally large number of icebergs moving off the coast southward; but, contrary to popular opinion, these ice masses and the swollen polar stream that bore them had no effect in lowering the air temperatures from Nantucket to Florida. Could the icy water have surged up against the shore, a different result would have been felt. We may, therefore, conclude that not only off Charleston, but possibly of Cape Cod also, there exists a submarine barrier projecting out into the Atlantic, intercepting the volume of heavy glacial water moving southwestward over the sea bed, and thus securing throughout summer the extraordinarily high temperature of 80°, which is observed in the western edge of the Gulf stream all the way from Cape Hatteras up to Nantucket shoals.

As these invisible features of the ocean floor off our coasts have an important bearing on the sea temperature and climate of the numerous seaside resorts from Cape Cod to Cape Hatteras, their accurate exploration is of growing interest and should be made complete.—New York Herald.

"THE CALIFORNIAN" FOR OCTOBER.—That rising popular monthly, *The Californian*, is making rapid strides toward perfection. The October issue, just received, is one of the most interesting ever published. Among the papers specially worthy of remark we notice the opening article, by Mr. W. W. Crene, Jr., who is now traveling in Europe, giving the first installment of the experiences of "A Winter in Berlin." Henry D. Wolfe has been "Cruising in a Chinese Man-of-War," and tells of the strange sights he saw. Mr. W. C. Morrow's thrilling story, "A Strange Confession," is continued, and grows in interest. Prof. E. R. Sill, of the University, under the title, "A Private Letter," reads us a telling lecture on our daily speech. John Murray has a discriminating criticism on John G. Whittier; Philip G. Galpin contributes a memorial on Gov. Haight; Capt. Edward Field relates "Some Incidents of the Seven Days;" Henry S. Brooks gives "A Scrap of Frontier History;" Marie Howland has an able account of "Education in Japan;" Alexander Del Mar formulates the railroad side of the controversy with the State; and a writer who signs himself "Lorelle," hints whom we suspect to be a well-known contributor, looks into the future, and, in a semi-humorous way, prophesies the result of Chinese immigration in the year 2080. Short stories are supplied by Sallie R. Heath and Mary W. Glascock, and some good poetry is contributed by Charlotte Perry, Seddie E. Anderson and Charles H. Shinn. The usual departments are added, and the number, as a whole, is very complete and satisfactory, and fully the peer of any magazine published. Our readers should bear in mind that by sending their yearly subscriptions to the *Californian* (202 Sansome St., San Francisco) before the first of the coming month, October, they can get it for \$3 instead of \$4. Don't delay, but send your subscription at once.

MRS. ATKINSON is succeeded in the superintendency of the Massachusetts State prison for women by Dr. Eliza M. Mosher, formerly physician of the prison and deemed capable of administering its affairs successfully.

News in Brief.

LARGE forest fires are reported southeast of Salt Lake City.

It is stated that Chilo has accepted the mediation of the United States.

A STEAMER from Baltimore for Liverpool lost 225 head of cattle on the passage.

THE Chinese portion of Auburn, Placer county, has been destroyed by fire.

GENERALS STEWART and Roberts have received the grand cross of the Order of the Bath.

A BERLIN dispatch says that Prince Bismarck has abandoned the project of a bi-metallic system.

MAIL service has been ordered on the new railroad between Bath Mountain and Austin, Nev.

AN electric light of 10,000 candle power now adorns the front of the Madison Square theater, N. Y.

A HUMAN skeleton was recently found near Hood river lodged in a tree 15 ft. from the ground.

PHILADELPHIA is to have a new club, composed of the amateur artists and musicians of the city.

THE Mexican troops are to immediately recommence the campaign against Victorio's band of Apaches.

A MEMBER of the Guards' Club, London, has been expelled for brutally beating one of the house servants.

THREE THOUSAND Smiths, alleged descendants of a man who lived 150 years ago, met recently in New Jersey.

THE London and Northwestern railroad was lately discovered to be mined with dynamite and gunpowder.

THE Emperor of Germany and his entire Court will visit Cologne, Oct. 15th, to officially open the cathedral.

THE mail bags on the Pecos mail line were rifled on Thursday night, Sept. 9th, near Anton Chico, New Mexico.

A FIRE in Saint Beat, Haute Caronne, Sept. 10th, has destroyed 32 houses and rendered hundreds of people homeless.

A DISPATCH from Rome, Sept. 10th, says a stream of lava is issuing from Mt. Vesuvius, near the new railway to the crater.

THE winter wheat crop of Illinois is 53,865,000 bushels, valued at \$44,457,000. Over 46,000,000 bushels are to be shipped.

OWING to tobacco worms and damaging rains, the tobacco crop in portions of Virginia will be the smallest known for many years.

It is said that fish recently caught in the Columbia river branded with letters were put in the Atlantic by an Eastern hatchery.

THE belief that the evacuation of Candahar would be the abandonment of all the fruits of war, has now become universal in India.

L. COLNATH and George M. Scott have been appointed Commissioners for Utah for the great world's exhibition in New York, in 1883.

LUCY TAPPAN, a graduate of Vassar and the Massachusetts normal school, takes the chair of mathematics at Lasell seminary, Auburndale.

THE stone lighthouse on the first point of Tanging-Koeling, on the west coast of Java, has been thrown down by a violent earthquake.

THE Irish Royal College of Surgeons has lately severely cautioned its members against having any communication with homeopaths.

A TRAIN from Waterloo station, London, for Hampton Court, came in collision with an engine. Four persons were killed and 30 injured.

HERR GERHARD ROHLFS, the explorer, is going to Abyssinia as a diplomat. He is charged by the Emperor William with a mission to King John.

MARTINEZ, a leader of the recent revolution in Sonora, has been arrested by a deputy United States Marshal for violating the neutrality laws.

M. GAMBETTA speaks very fast in public. Most men pronounce but about 180 words a minute, but M. Gambetta talks at the rate of 235 a minute.

WHENEVER members of the Chinese Embassy appear in the streets of New York they are hooted at and pelted with stones by the Gotham "hoodlums."

A MINER, whose name could not be ascertained, fell through a snow-bridge into Panther creek, in Washington Territory, on the 9th instant and was drowned.

A WOMAN in Root Co., Nev., the wife of a Justice of the Peace, the other day made the wedding cake for a couple her husband married, dressed the bride, and gave birth to twins.

A DISPATCH from St. Johns (N. F.), of Sept. 10th, says the British steamer *Anglia*, from Boston to London, foundered at sea, four days out on the 6th. All saved. Vessel and cargo lost.

A NEWLY married couple of Portland, Maine, were at a neighboring island the other day, when the husband played croquet with other young women. The bride fired a revolver at him, and he ran away and has not been seen since.

A POET, named Sarragin, finding fame did not come to him quickly enough, determined to make it. He has just astonished the city of Lyons by entering a cage of lions and reading one of his poems.

DR. O. W. HOLMES once perpetrated a pun in relation to the rival claims of the late Dr. Jackson and another physician to the discovery of anesthetics. He proposed that a single monument be erected to both jointly, on which should be inscribed: "Here's to ether."

By Universal Accord,

ATER'S CATHARTIC PILLS are the best of all purgatives for family use. They are the product of long, laborious and successful chemical investigation, and their extensive use, by physicians in their practice, and by all civilized nations, proves them the best and most effectual purgative Pill that medical science can devise. Being purely vegetable, no harm can arise from their use. In intrinsic value and curative powers no other Pills can be compared with them, and every person, knowing their virtues, will employ them, when needed. They keep the system in perfect order, and maintain in healthy action the whole machinery of life. Mild, searching and effectual, they are specially adapted to the needs of the digestive apparatus, derangements of which they prevent and cure, if timely taken. They are the best and safest physic to employ for children and weakened constitutions, where a mild but effectual cathartic is required.

FOR SALE BY ALL DEALERS.

Pocket Mining Atlas,

Containing the principal mining districts in the United States. Compiled from the latest official surveys and the most authentic sources by Edwin Bolitho. Sent, post-paid, on receipt of \$1. Address, Dewey & Co., 202 Sansome St., S. F.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omissions of agents.

IMPORTANT additions are being continually made in Woodward's Gardens. The grove, walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

BOUND VOLUMES OF THE PRESS.—We have new sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for \$3 per (half-yearly) volume. In cloth and either binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by seeing it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus, terms of subscription, etc., and request that they circulate the copy sent.

J. G. COLMERNEL is requested to report to this office. He went to Humboldt County, Cal., about May 4th, 1880. His Agency for this paper has been revoked for good and sufficient reasons. Mr. C. is a heavy set man, of dark complexion, weighing some 175 pounds, or more.

INVENTORS, and others interested, will receive DEWEY & CO.'S MINING AND SCIENTIFIC PRESS PATENT AGENCY Circular free on application at this office. It contains 42 pages of hints and information about Patents, Patent Laws, Patent Office Regulations, and how to obtain valid patents.

HOW TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

New Book on the Comstock.

The attention of MINING ENGINEERS and EXPERTS
is called to the new work by JOHN A. CHURCH, E. M. Ph.
D., on "The Comstock Lode, its Formation and History." This
very exhaustive treatise on this famous lode is fully
illustrated with diagrams and colored charts showing sec-
tions, ore bodies, etc., and will be of great interest and per-
manent value for reference. DEWEY & CO., Publishers of
the MINING AND SCIENTIFIC PRESS, are sole agents for the
sale of the work. Mr. E. M. SLEATOR will act as their
agent, and call on Mining Engineers and those interested in
the great lode in this city with a copy of the book for their
inspection.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot, PARKE & LACY, 21 and 23 Fremont Street. S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

Hoisting and Pumping Machinery.

STEIGER & KERR'S CONTINUOUS DISCHARGE AND GRINDING PAN.

This pan is designed to receive ore direct from a rock breaker, and reduce it to the fineness necessary for amalgamation, thus taking the place of the ordinary stamp battery. The cost of this Mill places it within the reach of all; and one point of advantage not to be overlooked is the fact that the cost of erection, which adds so much to the expense of the stamp mill, after it leaves the foundry is, in this case, reduced to a fraction, as the Mill is complete in itself, and requires no expensive foundations, bed logs, battery frames, etc., but can be placed in position in a few hours after it arrives on the ground, without the aid of skilled labor. This simple arrangement, durable as it is simple, is a most important improvement in the working of gold ores, as it enables parties to construct and erect a mill at half the cost of a stamp mill, and with a great saving of time, and size of mill building. Each pan is capable of reducing 10 tons of average ore in 24 hours, the ore being first broken in a rock breaker, small enough to go through a half-inch screen. There is an important point in the action of this Mill, to which we desire to call the attention of miners and millmen. We allude to the grinding and scouring action on the gold before it is discharged. The value of this point cannot be over estimated, and it is not necessary to do more than mention the fact, as it will be at once recognized by all competent millmen who examine the pan in operation, and especially by those who have had to deal with tarnished or rusty gold, as it is commonly called, and which is often encountered in our mines, and which is such a cause of loss. The pan of feeding is the same as in the stamp mill, either an ore feeder or hand feeding being adopted, as may be desired. Parties interested in mining and those who see the Pan in operation by calling at the **OCCIDENTAL FOUNDRY, STEIGER & KERR, 137 First St., S. F.**

SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Cross and Blackwell, London, &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

Well Tested Mining Devices.

GRATE BARS—Hydraulic. A saving of about half the usual expense. GROOVED RIFFLES—Hydraulic or quartz. Will largely increase the yield of gold. Concentrators No. 1 and 2. Former without machinery. Latter for fine Gold, Sulphate or Black Sand. BRYAN TYSON, Patented. Manufactured by Rankin & Co., Pacific Iron Works.

507 Mechanical Movements.

Every mechanic Should have a copy of Brown's 507 Mechanical Movements, illustrated and described. Inventors, model makers and amateur mechanics and students, will find the work valuable far beyond its cost. Sold by DEWEY & Co., Patent Agents and publishers of MINING AND SCIENTIFIC PRESS, San Francisco. Price, \$1, (post paid).

DUNHAM, CARRIGAN & CO.,

LIGHTNING SCREW PLATES

WITH TAPS, DIES AND COLLETS COMPLETE.

B, Stock 23 inches long, 7 Taps and Dies Cuts $\frac{1}{4}$ to $\frac{3}{4}$ inch.
C, " 26 " " 7 " " " " to 1 "
D, " 53 " " 6 " " " " to $1\frac{1}{2}$ "

No. O. Lightning Hand Bolt Cutters and Tappers.

ESPECIALLY FOR CROOKED WORK!

Made to be bolted to the Bench or Table. Fitted with seven sizes, from $\frac{1}{4}$ to $\frac{3}{4}$ inch. Usual assortment, $\frac{1}{4}$, 5-16, $\frac{3}{8}$, 7-16, $\frac{1}{2}$, $\frac{5}{8}$, $\frac{3}{4}$ inch.

SEND FOR CIRCULARS, COMPLETE.

Nos. 107, 109 & 111 Front Street, San Francisco.

DEWEY & CO.'S

Scientific Press

Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

The Wheelock Variable Cut-off Engine.

The mechanical industries of this coast are peculiar. They are not extensive yet, except in mining machinery and steam engines, but so far as gone, there is about them a broadness and boldness that has excited comment in other parts of the world.

The construction of machinery here is an "engineering" business as distinguished from a manufacturing one. There are more designs made and more mechanical draftsmen in San Francisco than will be found among ten times the "industrial" population in the Eastern States; and there are various works where orders will be taken alike for mining machinery, marine engines, locomotives, sugar mills or machine tools, and the work is carried out, too, in accordance with modern practice, including the best European as well as American precedents.

Situated as we are several thousand miles from analogous operations in the Eastern States, our engineers draw upon a wider field, and except Philadelphia, and there too, perhaps, there is no place in this country where the progress of engineering work in Europe is so closely watched as in San Francisco.

One thing we have been a little tardy in, however, that is, the highest economy of steam using. There have been no want of skill or knowledge of all data relating to the subject, but there has been a dread of the "refinements" in mechanism which the most improved steam engine involve.

The matter has recently been taken up, however, and the chances are that our engineers will not only attain as much as their Eastern or European competitors, but in the end, as in some other things, add bold improvements to astonish our slower-moving friends.

These remarks we make preliminary to some notice of the "Wheelock engine," illustrated in our present number. The engine has been engraved from a modification made at the Pacific Iron Works in this city, and, forestalling our reader's opinion, we think it a very creditable reproduction of this well-known engine.

The Wheelock engine, as many of our readers will remember, was exhibited at Paris in 1878, and in competition with some of the highest types of both European and American manufacture, carried off the chief honors, for economy, ease of action and simplicity of its valve gear.

The chief peculiarity of this engine, as contrasted with others having oscillating valves, is that they are in effect balanced, being supported on trunnions or spindle, that relieve the valve seats from undue pressure and permit a movement almost devoid of friction.

We are well aware of the failures in many attempts to "suspend" valves; that is, to keep them off their seats in so far as steam pressure on the back, but now that 10 years of duty in various parts of the world has proved the practicability of the "Wheelock" method there is nothing left but to take the fact for granted.

Moreover, it must be remembered that even in case of failure of the concentricity of the supporting stems the valves are then left in the same condition as in common slide valve en-

gines or the common type with oscillating valves.

We will not, however, enter upon the mechanism of the valve gear or the valves farther than to mention that the cut-off is an independent valve. These are matters of detail, problems of good-fitting and honest workmanship.

The Corliss engine has demonstrated since 1856 or thereabout, that variable valve gear could be made sufficiently durable and reliable to meet the requirements of ordinary use. The whole engineering world has followed this, an American idea, in steam, until the practicability, as before remarked, is no longer a question.

Referring further to the engine shown, Messrs. Rankin and Brayton, after very careful investigation, selected this valve movement as the one, in their opinion, best suited to the purposes of this coast, and by having added considerable strength to various parts of the engine, have carried out a design which does them and our

New Manufacturing Agencies.

The Pacific Coast Agency of the celebrated Knowles pumps, has within a few weeks been transferred to Messrs. Parke & Lacy, dealers in mining machinery, Nos. 21 and 23 Fremont St. They will now carry a full line of these pumps in stock, from the largest mining pump to the smallest made. This firm has also received this month the agency of another important manufacturing establishment, that of Scott Broe, engineers, wire drawers and manufacturers of improved steel and iron wire ropes for deep shafts, inclines, mines, shipping, telegraph wire, etc. Messrs. Scott Broe make a special patent steel wire cable for underground haulage, street railroads, conveyance of heavy loads, and all purposes where transmission of power is

Defective Safeties.

Another mining accident; nine men were killed; cause, defective safeties. How many times has this been chronicled, and how many times will it still be repeated? On this occasion the occurrence was at the Imperial mine, as detailed elsewhere in this issue, the cage being precipitated down the shaft with its living freight. The cause of the accident is only surmised, but the fact is apparent, upon examination of the guides, that the safety clutches on the cage did not catch once from the time the cable broke, although the foreman reports that they were in good condition. The *Enterprise* says it is thought that the falling cable coiled upon the top of the cage in some such way as to prevent the springs of the safeties from acting. Be this as it may, the safeties evidently did not work at all for some reason, as there are no marks upon the guides such as would be made had the cage stopped and then been forced down by the weight of the cable falling upon the bonnet. The blacksmith at the works, who is considered one of the very best on the Comstock, says he is positive that the safeties on the upper cage were all right, and he is unable to account for their failing to catch, if indeed they did fail. The springs attached to the safeties are of spiral-coiled wire, but stiff enough to hold a man's weight, and would surely move the eccentric if not interfered with, or in some way overcome. He says he has also used the usual steel springs, oiled like a watch spring, but prefers these now in use at the mine.

The truth of the matter is, that upon the action of a spring men's lives should not be made to depend. Springs cannot always be depended on by any

means, as this and many other instances prove. There are other mechanical appliances of more positive action than springs, which ought to be used on these cages.

The cable was nearly new, having been but about three months in use—of the best steel wire, and English make, four and one half inches by one-half. It was considered the best in the works, and had never been used to raise rock. It was also ascertained at the works that only last week the pitman of a pump, weighing from 2,500 to 3,000 lbs., had been safely lowered by it. The broken ends of the cable show the strands to be in good condition, only a few exhibiting signs of crystallization. It was considered perfectly safe, and the parting can be accounted for in no other way than by a sudden strain. It is strange, too, that it broke near the reel, in the portion least used.

ALL the Paris papers agree in advocating a pacific foreign policy. Some journals demand the Chamber to be summoned for a special session; but it is impossible. They will not meet before the usual time. It is announced that as soon as the new Cabinet is definitely constituted, a circular of a very pacific character will be dispatched to the representatives of France abroad. It is announced that Gambetta will shortly deliver a pacific speech.

Edison will soon have another test of his electric light.

THE WHEELLOCK VARIABLE CUT-OFF ENGINE.

San Francisco establishments credit. We are always glad to note whatever indicates progress in our mechanical industry, and the adoption of variable cut-off gear is certainly in the line of such progress.

It is easy to see a time, Mr. Isherwood to the contrary notwithstanding, when the expansive principle will be carried to its fullest extent in stationary, as it is in marine engines.

The high cost and scarcity of fuel on this coast will, in the end, as we have before indicated, no doubt lead to a great economy in steam using. It must do so, and there is at this time connected with the subject no matter of more importance than expansion.

We except, of course, economic evaporation and boiler plant, but between the two we must attain a duty of two pounds of coal per horsepower per hour before the problem can be called exhausted. The makers inform us that in a large cotton mill in Georgia a Wheelock engine is approximating this, and if so, we must accept it as an evidence of great merit in both steam making and steam using appliances.

The engraving was taken from an engine constructed for the Boston & Arizona Co. mill recently erected at Contention City, Arizona, the cylinder 20 inches in diameter, with stroke of 42 inches.

THE master weavers of north and northwest Lancashire have resolved to run but three days a week.

effected by means of endless traveling wire cables. The wire for this rope is manufactured by special patent process, has a very high direct breaking strain, and a hard tempered skin.

The firm make very large quantities of wire rope for mining purposes. One of their latest jobs is in the Cymmer colliery, Rhondda valley, Glamorganshire. Here there are two shafts, one of which turns out 1,500 tons a day and the other 800 tons a day. The drums for the hoisting ropes are respectively 11 ft. and 16 ft. and 6 inches in diameter, the hoisting ropes being of patent plow steel wire, supplied by Scott Broe. The underground haulage is on the endless rope principle, single walks, slow speed, comprising all the latest improvements. Scott Broe manufacture galvanized iron and steel rope for rigging purposes in large quantities. Their rope took the only prize medal at the Havre Maritime-International exhibition in 1868, since which time they have introduced many improvements. Messrs. Parke & Lacy will very shortly have on hand a very large and complete stock of this English rope for ships' rigging, flat rope for mining, hoisting, hauling rope, etc.

THE five big bridges of the Texas and Pacific railroad at the end of the track, 122 miles from Dallas, were finished on the 21st and trains ran beyond Palo Pinto canyon. Immense quantities of construction material are now passing to the front.

Certain Parasitic Plants.

[Written for the PRESS by W. G. KLEW.]

The process by which plants obtain their aerial food, and by which, in the leaf, carbonic acid is decomposed into its two constituents, solid carbon and oxygen gas, is termed assimilation. This wonderful power so wisely given plants, is not extended to all of them; it is only to those that contain leaf-green (or, as it is called, chlorophyll) that it is given, and then only under the influence of light. Plants that contain chlorophyll are not necessarily of green appearance; covered with thick white down or waxy excretions, it is sometimes concealed, or the presence of a coloring matter prevents it from being seen. These, however, must be considered the exceptions, and as a general thing a plant that is not green, must be considered a suspicious character—that is, not able to make an honest living. They are, in fact, the robbers and thieves among plants. These so-called parasites are of two distinct kinds: 1. Those that live on decaying or diseased vegetation; 2. Those that take the already prepared life-sap as it flows and appropriate it for their tissue. Into the mystery of the first class, to which the well-known fungi belong, I shall not enter, but turn to those peculiar adaptations among higher plants that live on the hard-earned nourishment of their fellows.

As a general thing parasites are not green, but there exist, nevertheless, some; and as discovery in botany has advanced, there has become known a number of green half-parasitic plants, formerly thought to be independent, that are root-parasitic on other plants, though generally not all their lifetime. These then form the transition to the more reduced parasites. It is among the family of *Scrophulariaceae* that we naturally should find these plants, for closely allied to this we have the order *Orobanchaceae*, which consists of a large number of true parasitic plants. In Europe the *Euphrasia* (*E. Odontites*, Eyebright) has been considered dangerous to the rye, and another, *Rhinanthus* (*R. Cristagalli*, Yellowpattie), has been the plague of the barley. Here in America we have two conspicuous examples, the *Gerardia*, with its beautiful yellow flowers, and the *Castilleja*, a native of the Eastern States, as well as of this coast. Its name at the East is "painted cup," while it is generally known as the flame flower in California, where its bright scarlet flowers, surrounded with scarlet or yellow bracts, attracts everybody's attention.

In another quite different family we have the *Comandra* (the bastard toad-flax); also occurring in California. This has a yellowish-green color, and entire oval leaves, resembling considerably its arboreal relative, *Santalum*, of India and Australia. *Santalum* is not parasitic when quite young, and will grow for some time without support; besides this there are several other genera belonging to *Santaleaceae*, but the *Santalum album* is the most important, yielding the true sandalwood. Naturally related to the latter, we come to that of the mistletoe. These are old well-known plants. The European species, *Viscum album*, has from time immemorial played a part in the world. Not taking in consideration that its berries have furnished the bird-catcher's bird-lime, it has perhaps done more mischief than any other of its kind; for was it not by means of the mistletoe that the evil one, Loke, of the Scandinavian mythology, caused the best of the gods, Balder, the personified Kindness and Love, to be killed by his blind brother. Whether the custom prevalent in England to give the privilege of kissing under the mistletoe hovers at Christmas, the cause of less mischief, I shall leave to the fair sex to decide. The various genera of mistletoe, *Viscum phoradendron* and *Loranthus*, make forest trees as well as cultivated ones their victims. The seed is naturally carried by birds, to whose beak it sticks and is deposited in a crack by the bird trying to clean its beak; roots soon develop and penetrate deeply into the cambium and wood of the tree, soon forming as close and intricate a connection as if it were a branch of the tree itself. Once inserted this way, it is pretty hard to destroy without cutting off the branch and all. Here in California the mistletoe seems to prey mostly on oaks, chiefly on the white oak (*Quercus lobata*), which it often completely kills. It would be desirable to stay the spread of this evil by preventing it from seeding. In Australia occurs the genus *Loranthus*, that is a tree ornament, though a dangerous one, by its brilliant scarlet flowers.

Leaving the green parasites, we pass to the class of parasites that are destitute of chlorophyll, or leaf-green, and consequently only can live by drawing the elaborated sap from their hosts. I have mentioned before that closely allied to *Scrophulariaceae*, the family among which there was found a number of half-parasitic herbs, we find one of the largest orders of colored parasites, the *Orobanchaceae* or *broomrape* family. This is chiefly of the old world, but there is found several representatives of it here in the U. S. Of these the *Epiphegus* or beechdrops, a purplish-brown colored herb, is found on the root of the beech, and the cancer-root, of similar appearance, flourishes among the oak. The *aphyllon* (*Orobancha*) is found in the Eastern States, as well as here in California, where the species *A. Californicum* preys on the roots of the *Chemisa* or *Adenostoma fasciculatum*. It

is a brownish-purple fleshy plant, with scales on the roots, where it has attached itself; all further growth beyond the attachment ceases, and it is therefore found on the end of the roots. The flowers of this species are purple, with an agreeable perfume. Other species of similar aspect occur on other plants. Another family where colored parasites occur is that of *Ericaceae*, or the heath family. Among those found in America are the well-known pinedrops (*Pterospora*) and pinesap (*Schweinitzia*), in aspect resembling the members of the broomrape family, but distinguished by the typical heath flower. The Indian pipe or corpse plant (*Monotropa*) is of a delicate waxy white, and singular prominent in a dark, shady forest, where it is found on the roots of various trees. It is, however, in the mountains of California we find the most beautiful and remarkable of this family, the famous snow-plant, *Sarcodes sanguinea*. Unlike most of the parasites of the temperate zone, it is marked by a beautiful pink color, bordering on crimson, and when seen, as it often is, with the snow as background, or surrounded by snow, it is a sight not easily forgotten. The strong fleshy shaft shoots often up several ft. before reaching the surface. The bell-shaped, red, waxy flowers are often one-half inch long, each having a fringed bract at the base, and the huge raceme, that reminds some of a very large pink hyacinth, is often a ft. long. When taken away from its support undeveloped and placed in sand, it will unfold its flowers, but of course not live after all assimilated matter stored in the fleshy stalk has been consumed.

But another still more interesting in botanical respect is the *Pyrola aphylla*. *Pyrola* is the so-called winter-green, a genus of pretty evergreen shrubs. In the *Pyrola aphylla*, as the name indicates, the leaves are lost or rather transformed to scale-like units for the true office of leaves, and the plants, therefore, form parasitic attachments, linked closely to the bright winter-greens; it forms thus a true transition from these to the before-named parasites.

Under the head of parasites, with remnants of leaves in form of scales, there are still two families of parasitic plants of general interest—the first (*Cytisaceae*) worth mentioning, on account of the attractive appearance of its members, which nevertheless ought not to favor their introduction, as they are pernicious parasites that had better be left in their native country—southern Europe and north Africa. Well-known among these is the *Cytinus hypocistis*, parasitic on the *Cistus* or rock rose, as the name indicates. The second is the *Balanophora* or spathe-bearing parasites. They are close allies of the *Arum* family, which they resemble in many respects, but in that of not being provided with leaf-green. Unlike most parasites, we count its members among several of considerable usefulness, which somewhat justifies their peculiar mode of living.

The *Langsdorfia hypogaea* yields, in New Grenada, an abundance of wax that is manufactured into candles. In Bogota is the species there known as *Sipo*, utilized as a torch. In Java there is likewise derived a kind of wax from *Balanophora elongata*. Having now dwelt on the colored parasites, that though not provided with leaves capable of any assimilation, still in the form of bracts or scales show plain evidence of these, we step down still lower to certain plants, where, in the embryo, even there is scarcely any sign of leaves. I refer to the too well-known dodder; it is superfluous for me to dwell long on the description of these plants; their yellow tangles have too often discouraged many a farmer; seen it destroy his flax field or clover. Here in California the species infesting the clover has long ago found its way to the alfalfa field. Farmers cannot be warned too often for this seed, and as a little close examination of it will reveal the true nature of it, it is, as stated, destitute of catydoledon (seed leaves), a spirally-curved thread, with a few scattered, very minute, scales being all that is present, so that even in the embryo the peculiar aspect is foreshadowed of the mature plant. The danger of the dodder spreading is of course counteracted by the fact that the various species prey, as it seems, only on nearly related plants. There exist, however, Californian species that seems to prey on very different plants, for instance the live-oak (*Quercus agrifolia*), poison oak (*Rhus lobata*), groundsel tree, *Bachoris*, and might be liable to attack cultivated plants. The adaptability of the dodder species to all localities, from the salt marshes of the bay to the dry hills, seems to justify this apprehension, and it should, therefore, be pursued as a thief and robber that might be liable to attack you anytime.

In this connection I cannot pass a very curious and interesting case that I learnt the other day. The small white morning glory is a too well-known weed that threatens to be a pest in some places; many remedies have been tried, but short of picking every piece of root out nothing seem to be complete. An ingenious nurseryman hit upon the bright idea to employ the dodder as an exterminator of the morning glory, and according to his statement it did its work remarkably well, killing off its near relation very fast. If this species of dodder employed thus is not the same that preys on the clover tribe we shall after all have to take the robber as an ally; but if it is the same the remedy is a little too dangerous to be a safe one.

Demising the pernicious leafless yellow relative of the morning glory, we step down a step

*The dodder *Cuscuta* belongs to the family *Cuscutaceae*, a sub-order of the morning glory family *Convolvulaceae*.

still lower and leave behind roots, leaves and stems until we find but the flower left. Plants consisting of nothing save one solitary flower. These vegetable wonders constitute the family of *Rafflesiaceae*, and are chiefly natives of Asia, though some are found in Chile. They vary in size from very minute until in the tropical jungles of Sumatra and Borneo they reach the largest size of any other flower known. The largest of these giant flowers is the species *Rafflesia Arnoldii*, which was first discovered by Dr. Arnold, who as naturalist accompanied the Governor, Sir Stamford Raffles, in Sumatra, and he relates it as follows: "I had accidentally absented myself from the party, when a Malayan servant came running up to me and with expression of the greatest surprise cried out, 'Come with me, sir! Come along! A flower very large, very fine, very wonderful!' I followed him a hundred paces into the jungle, where he pointed out to me between the bushes near the ground the most remarkable flower. It was attached to a slender, hardly two fingers breadth, thick root. I loosened the flower with Malay's parang, and bore it to my tent. When I saw it first there was a swarm of flies around probably seeking to deposit their eggs, as it had all the smell of decaying meat.' This *Rafflesia* is parasitic upon a *Cissus*, a relation of the grapevine; it has a perigonium (set of floral leaves), with five large lobes, thick and fleshy, brick-colored, with white warts; at the base of the lobes of the floral leaves is a kind of rim, and inside are found the numerous stamens. The fruit of this plant is a globular berry, containing numerous small seeds. These are probably carried by large insects or birds and deposited in cracks in the vine; here in the damp atmosphere it soon develops and is completely enclosed, until, like a boil, it bursts through the bark and enfolds itself, reaching sometimes a diameter of 3 ft. and a weight of 15 lbs.

Taking the parasites as a class, they are of more than usual interest to the student of nature. They illustrate wonderfully the adaptation of organisms. Though so reduced in their form, they fall more or less naturally into the orders of plants, and proclaim thereby that they are developments of the same nature and conceived in the same spirit as other plants.

Berkley, Cal.

Tin Ore in Maine.

The most important development in mining which has taken place in the State of Maine is that of tin. The country has no lack of mines of gold, silver, copper, lead; but as regards tin the case is very different. For that valuable metal we are obliged to go abroad, chiefly to England; and so long as that country controls the market for tin there is little hope of our warring from her the larger traffic in tin plate. The development of tin mining at home to a degree sufficient to secure the practical independence of our vast industries employing tin and tinned iron would be worth much more to the country, indirectly if not directly, than any mine of gold or silver. Accordingly it may be safely said that the announcement of the discovery of extremely promising deposits of tin ore in Maine is likely to awaken a heartier interest throughout the country than any other mining reports from that land of mining hoome. If any one of Maine's mineral products fail, it is sincerely to be hoped that the failure will not be in tin.

Indications of tin were discovered in Maine some 10 years ago, but then it was the popular belief that Maine was not, nor ever could be, a mining State. Recent explorations in the town of Winslow, on the Kennebec, a few miles above the State capital, have discovered half a dozen metallic veins of rich tin ore, in a rock formation precisely like those in which tin is found in Cornwall, Germany and New South Wales.

As described by Prof. C. H. Hitchcock, the rock which encloses the tin ore of Winslow is a mica schist or killas, associated with somewhat calcareous layers, and adjacent to a hard quartzite band, called an *elvan* by miners. Thirty ft. width of vertical schists of killas show 12 granite veins from half of one inch to three inches width, crossed, occasionally, by stragglers. These veins are full of crystals of tin ore (cassiterite) with the associated minerals fluor spar, margarite, mispickel, heryl, lepidolite, etc. The mineral, geological and physical feature of the Winslow mine are, Prof. Hitchcock adds, "identical with those common to the stanniferous districts of Europe," and "the ore seems to be sufficiently abundant to remunerate quite extensive outlay for mining operations."

Prof. Forrest Shepherd described the mineralized belt at Winslow as from 30 to 40 or more ft. in width. In a shallow pit where it has been uncovered, five or more veins appear within a space of eight ft., a promise unequalled in any Cornwall or Saxony mine. And what is particularly encouraging, the Winslow deposits are, at the surface, equal in quality, Prof. Shepherd says, to the best in Cornwall, and in a series of veins most favorably situated, while in Cornwall and elsewhere the veins are rarely remunerative except at great depths.

A company has been formed to develop the Winslow mine and to extend the explorations for tin in other parts of the State. The prospect of success is, to say the least, very encouraging. Should the yield prove abundant a particularly favorable opportunity would seem to offer for the manufacture of tin plate in that State, owing to the abundance of suitable iron ore and the proximity of forests for supplying the charcoal required to smelt it. —Scientific American.

The Greatest Deposit of Iron Ore in the World.

[From Notes in Iron Age of the Lake Superior Meeting of American Mining Engineers.]

We have scarcely dispatched breakfast when we glide into the harbor of Escanaba, already the principal shipping port for iron on the lakes, and with the promise of a future which would warrant much more extravagant prediction than its citizens are disposed to make. To-day we are to see the mines of the Menominee range. We have heard of them with more or less interest, but have seen so much ore on our trip that most of us would willingly pass the Menominee district by and go on to Chicago. We are all tired and it rains. But from the first glimpse of one of these mines the lagging interest revives and becomes almost an excitement. We have questioned the propriety of calling some of the great openings of the Marquette and Negannee districts "mines," as they might with more propriety be called "ore quarries;" but what shall we call these Menominee openings? They are not even quarries. You strip off the surface, and beneath lie deposits of ore such as the eye of man hath not seen. We are amazed, astounded, confused. Some of us who are interested in Eastern mines even turn away disgusted; and what wonder, when we see miners working these vast deposits of steel ore with pick and shovel as easily as they would dig a cellar on a sand hill; when we see ore of unapproachable richness and purity loosened, loaded and put in cars for 25 cents a ton, including everything except the royalty of 50 cents. We have been impressed from the first; now we are appalled. I do not exaggerate in any respect the feelings of those who saw these mines for the first time on Tuesday, and who had enough acquaintance with the iron trade to understand the meaning of what they saw. "There is nothing like it in the world," says every one, and no one can intelligently question the statement that in this Menominee range, with its incalculable wealth of ore in sight and its unlimited possibilities of development, has been found the solution of the ore question for a longer time into the future than anyone now in the iron business has any occasion to look. Many will probably read these words with a smile. A week ago the writer would have smiled had he read them from the pen of another, but the smile would disappear could the reader see these things with his own eyes. Description cannot do justice to the subject, any more than it could to the Falls of Niagara. Even when we see the Falls we wonder how this mighty cataract is fed, and when the supply of water which pours over the precipice in never-diminishing volume will be exhausted. But our question is answered when we cross the great inland seas which are its unfailing fountains. So it is with Lake Superior iron ores. We see them steadily flowing into the port of Cleveland in increasing volume, and have allowed ourselves to be deluded by the mistaken predictions of such authorities as Mr. Bell, that they are drawn from pockets of known extent, and that the end of the supply can be predicted. When we go and look for ourselves we see that the supply is not a matter of years, but of centuries; that as yet we have but scratched the surface of a mineral wealth for which the world has no parallel, and that within two or three years at most, the abundance and cheapness of these ores will so reduce the cost of iron as to materially change the condition of national industrial development and international competition. If anyone doubts this, let him go and look, and his eyes will be opened. For the first time your correspondent appreciates the value of the Lake Superior ores as a factor in the problem of our iron development.

The Menominee range is the latest and grandest development of this wonderful country. In 1877, 10,405 tons of ore were shipped; in 1878, 94,245 tons; in 1879, 269,089 tons. This year there have already been shipped 375,000 tons, and before the close of navigation between 500,000 and 600,000 tons will have gone forward. Every lb. of this ore will make Bessemer iron. The average cost at all the mines will not exceed \$2 per ton on cars. In the furnace they will melt like snow. In one instance the ore costs 20 cents a ton at the surface, and with a total force of 60 men at work the mine yields 400 tons per day. Nothing is shipped which does not contain 55% of metallic ore or over. The 50% ore is piled near the workings in the expectation that in the event of a sudden demand it may be wanted. This production can be increased as rapidly as it may be needed, and there will soon be no room for foreign Bessemer ore in a market so abundantly supplied from Michigan and Wisconsin. The time is not far distant when this ore will be delivered at Cleveland at \$4 per ton, leaving the mining companies \$1 per ton profit. At this point the purest ore will meet the Connellsville coke, the finest metallurgical fuel in the world, and the pure magnesian limestones of the lake shores, than which there are no better. The rest may be guessed.

A FINE ART publisher in London announces a public competition of original designs for Christmas and New Year cards, similar to that recently held in this city. Fourteen prizes are offered, amounting altogether to the value of \$2,500, and the judges are Sir Coutts Lindsay, Mr. Boughton and Mr. Marks—all artists. The designs need not be appropriated to Christmas or the New Year only, but they must have some suitable sentiment expressed in words.

MECHANICAL PROGRESS.

Methods of Boiler Making.

The government has spent thousands of dollars in experiments to discover the cause of boiler explosions; and the boiler insurance companies have gathered and published a prodigious amount of valuable facts and opinions about the behavior of steam generators, under various peculiar circumstances, for the information of boiler makers and steam users. Experts have advanced and bolstered up by argument a number of plausible theories about explosions, each endeavoring to pull down the theories of the others. But what is the general result of all these investigations? In one respect they agree. The opinion is unanimous that a boiler constructed of poor materials and of poor workmanship is quite likely to give trouble, and is liable to cause a serious accident, even in charge of a competent engineer, while a boiler of good material and well made is virtually safe. A very large proportion of boiler owners will not engage competent and careful engineers to manage them; therefore, the efficiency and reliability of the boiler must, or should be assured in the shop where it is made. But it is not altogether owing to carelessness or lack of skill among boiler makers that so many weak and dangerous boilers are made and sold, and go into use where they are believed to be safe.

Competition in taking contracts leads to some extraneous risks. Almost any boiler maker will study to produce a good, reliable article for the price agreed upon, making suitable allowance for the cost of material and work of construction. Steam boilers can be made better and at less cost than they now are by improving methods of manufacture. Boiler shops, as a rule, are not remarkably progressive in adopting new machinery and methods for facilitating and improving their work. The workmen often resist attempts to introduce labor-saving devices into boiler shops, though, as graphically depicted by Chordal, in a late issue of the *American Machinist*, successful devices of that kind contribute to give more work and higher wages. Holes in boiler plates are usually punched, thereby weakening the plates 35% to 40%, while by drilling the holes from a third to a half of this loss can be obviated. But, by common methods, drilling is much more expensive than punching. What is needed is a machine capable of drilling several holes at once, and which will work automatically. Such a machine would be one of the most desirable equipments of a boiler shop. Steam, hydraulic and pneumatic riveting machines are in use, each proving efficient and economical, but most shops adhere to the slower and more expensive process of hand-riveting. Flanging machines have been built, but, so far as we can learn, none have yet come into regular use. The successful development of a flanging machine offers a promising field for mechanical labor and experiment. Machines for bending plates are everywhere in use, but some of them are slow in operation. A machine for cutting off stay bolts quickly and without injury would be a very desirable adjunct to a progressive boiler shop, but we believe none have been successfully constructed thus far in this country, though they are in use in England. Hoisting apparatus is generally neglected in boiler shops, though a few shops are properly fitted up with such appliances.

Happily, modern improvements in the manufacture of boiler plates and tubes are such that a better article can be furnished for the price formerly paid for common stock, thereby encouraging boiler makers to improve their methods of construction. We look to see substantial progress in this direction. The shops that are enterprising enough to adopt the most radical improvements are those that will do work the best and at the lowest prices with satisfactory profits. They will also, as a natural consequence, secure the heaviest orders.—*American Machinist*.

The Gases Contained in Blow-Holes in Steel.

During a discussion following the reading of a paper on the Jones method of compressing fluid steel, before the Institution of Mechanical Engineers, Mr. E. Windsor Richards, the well-known metallurgist of Messrs. Bolckow, Vaughan & Co., gave some facts gathered at the Eaton Steel Works. Experiments were made to ascertain the composition of the gases contained in blow-holes of steel ingots, and Herr Mueller's results were fully confirmed. A tank was made sufficiently large to contain an ingot, this tank having a stuffing-box at the bottom through which a drill could be introduced. The ingot to be experimented with was placed in the tank, the latter being filled with water, and a hole 2½ inches in diameter was then drilled up 4½ inches into the bottom of the ingot. This drilling resulted in the release of gases, and the gases so evolved were collected and analyzed by Mr. Stead, of Middlesbrough, when the composition was found to be as follows: Hydrogen, 78.6%; nitrogen, 20.4%; carbonic acid, 0.2%; and carbonic oxide, 0.8%. From the hole just mentioned no less than 18 cubic inches of these mixed gases were obtained. We may add that Mr. Richards exhibited photographs of ingots planed down in the middle to ascertain whether they were sound or

not. One had not been compressed with steam, a second had been subjected to 80 pounds, and a third to 130 pounds. From the fact that the latter contained bubbles, it followed that a higher pressure of steam was desirable. It was therefore concluded to use a boiler capable of sustaining 200 pounds per square inch. It is not stated what grade of metal was subjected to steam pressure. Experience at the Edgar Thompson works has shown that for ordinary rail steel 100 pounds per square inch is sufficient. In conclusion, we may state that the claims to priority by M. Considere, who experimented at Chalosseire, France, were again brought forward during the meeting, but it was shown that Mr. Jones anticipated him.

Reducing the Consumption of Coal.

Engineering theory and practice have for a long time plainly pointed to high steam pressures as one of the surest ways to economy of fuel. Twenty-five years ago our ocean steamers carried only 16-lb. pressure to the inch, and burned 5 to 6 lbs. of coal per hour per horsepower. To-day they are carrying 75-lb. pressure, and burning 2½ to 3 lbs. of coal per hour per horsepower. In 1840 the *Britannia*, one of the finest steamers of the Cunard line plying between America and England, burned 5,291 lbs. of coal for each ton of paying freight she carried, her speed, then considered fast, being 8½ knots per hour. In 1877 the *Britannic*, speed 15.6 knots per hour, burned only 551 lbs. of coal per ton of freight carried. Although our present steamers are making fast time and are very economical as compared with the earlier vessels, still it is a lamentable fact that on the largest and finest of them, furnished with all the latest improvements and best appliances to secure economy, worked by the most careful and intelligent engineers, we succeed in putting into our steam only about one-tenth of the heat realized in our boiler fire, the remaining nine-tenths of the heat being lost. Only in proportion as we make our steam hotter and expand it more, shall we economize in fuel. In this respect the voyage of the *Anthraxite* is designed by her owners, we presume, to be an eye-opener for steamboat owners, not only in this country but throughout the world. If a little bit of a boat like this, 84 ft. long, 16 ft. beam and 10 ft. deep, can carry its own coal and water across the Atlantic, with a pressure of 350 to 500 lbs. to the inch, and on one pound of coal per horsepower, the natural inference is that our great steamers, when fitted on the same system, will realize far better results. The change from three pounds of coal to one pound of coal per horsepower means a saving of two-thirds in the coal bill, which is always an enormous item in the expense of large boats.

FILES AND FILING.—The following information may be found useful to some of our readers. A new file should always be used with light pressure on the work until the needle-like points of the teeth are worn away; after this a much heavier pressure may be used with much less danger of breaking off the teeth at their base. Many new files are violently diminished of half their efficiency by a few careless strokes when first applied to the work. Do not use a file on the chilled and gritty skin of castings, or on a weld where borax or any vitreous fluxes have been employed—no file can endure such usage. Every filer should keep a worn file with which first to attack the rough, gritty, or oxidized surface of iron work, and thereby pave the way for more efficient work with his sharp files. A piece of gritty or chilled casting that would rapidly destroy the cutting qualities of a new file would produce scarcely any damaging effect to a worn one. In filing steel, better results can generally be obtained by using files of a grade not coarser than "2d cut," finer grades being employed according to the finish and delicacy of the work under manipulation. Users of files should always seek to discover the fitness or adaptability of cut and form of files specially suited to their work. No one should expect the best results from a file on brass or spelter which was intended for use on iron and steel. Care should be taken when purchasing files to see that the manufacturer furnishes full weight articles. This is always a desideratum, and especially in case re-cutting is desired. A full-weight file can be re-cut two or three times, while a light weight will hardly bear one re-cut and give satisfaction.

EUROPEAN IMPROVEMENTS IN ELECTRIC BATTERIES.—European journals note two recent improvements in electric batteries, one of which is a modification of the well-known Bunsen, due to M. Azapis. It is stated that he has succeeded in reducing the consumption of zinc and effecting greater constancy of the current by using a solution of cyanide of potassium, caustic potash, chloride of sodium or sal ammoniac, instead of the dilute sulphuric acid generally used in the zinc cell. The second battery referred to is that of Woebler, which is described as follows: A roll of sheet aluminum is placed in a round glass vessel containing very dilute hydrochloric acid or dilute caustic soda. Within this large roll of aluminum is placed a porous cell containing concentrated nitric acid and a smaller roll of aluminum. Each roll has a lug or projection, which is inserted into a circular cover of ebonite, and thus kept in place,

SCIENTIFIC PROGRESS.

New Minerals.

Pandermite, a new beracic mineral, is described by C. G. Warnford Lock, in the *Journal of the Society of Arts*. He says that, through its geographical position, abundance, cheapness of working and easy manipulation, it is certainly destined, in a great measure, to rule the markets of Europe. The new field lies on the Tubiar-seu, a small stream feeding the Rhynadus river, whose outlet is in the Sea of Marmora, near the port of Panderna, on the Asiatic shore. It occupies an area of 20 square miles, and the stratum has been found to be 45 ft. deep. As well as observed, the name of the mineral is derived from that of the port.

In regard to the present state of our knowledge of the (so claimed) new elements, which have of late been announced with such startling rapidity, Mr. Humpidge contributes to *London Nature* a communication which is condensed by the *Engineering and Mining Journal*, as follows:

Of *Davyum*, which was announced in July, 1877, by Sergius Kern, as a new metal belonging to the platinum group, the author thinks that the investigator failed to take the necessary precautions to get rid of iron and the platinum metals, or at least that he does not state the means he adopted to do so. He holds, therefore, that this alleged discovery may be safely ignored.

The numerous metals of the yttrium group that have been announced are more difficult to discriminate between, because of their close relationship.

He goes into considerable detail in analyzing the claims of these numerous announcements to recognition, and presents the present state of our knowledge of them in the following scheme, which shows their status at a glance:

NAME.	Symbol.	Atomic Weight.	Discoverer.
Scandium (doubtful).....	Sc = 45.....		Nilsen.
Yttrium.....	Y = 89.....		Bunsen.
* Phosphium.....	Pp = 111.....		Delafontaine
* Unnamed metal.....	Atomic wt. {		Soret.
* Thulium.....	undetermined {		Cleve.
* X of Soret.....	Atomic wt. {		Soret.
* Holmium.....	undetermined {		Cleve.
* Terbium.....	Tr = 177.....		Marignac.
* Samarium (doubtful).....	At. wt. und. {		Boisboudran
* Decipium (doubtful).....	Dp = 159.....		Delafontaine
* Y Beta.....	149.4.....		Marignac.
Y Alpha.....	156.7.....		Marignac.
Erbium.....	Er.....		Mosander.
Ytterbium.....	Yb = 172.....		Marignac.

(Phosphium, the unnamed metal of Soret, Thulium, X of Soret, Holmium, Samarium, Decipium, Y Beta and Erbium give distinct absorptive spectra.)

Two alleged discoveries by Dr. Lawrence Smith, one of an earth unnamed, in the gadolinite of North Carolina, and another, which he alleged to be identical with the X of Soret, are not recognized by the author.

Of *Norwegium* and *Vesbium*, Mr. Humpidge says that, for the present, the chemical world must suspend judgment, since up to the present time we are without confirmation of their existence.

We are, as will be observed from the above, gradually finding our way out of the labyrinth of conflicting and duplicated discoveries which have puzzled chemists so much for the past few years, and may reasonably expect to see in the near future the wheat separated from the chaff.

* t, i.—probably identical.

THE EARTH AS A CONDUCTOR.—In a paper on the earth as a conductor of electricity, Prof. Trowbridge, of Harvard, arrives at these conclusions: 1. Disturbances in telephonic circuits usually attributed to effects of induction are in general due to contiguous grounds of battery circuits. A return wire is the only way to obviate these disturbances. 2. The well-defined equipotential surfaces in the neighborhood of battery grounds shows the theoretical possibility of telegraphing across large bodies of water without the employment of a cable; and leads us to extend greatly the practical limit set by Steinheil. 3. Earth circuits have an intermittent character, with periods of maxima and minima, which may occur several times a minute during the entire day. This intermittent character is seldom absent.

AN ADJUSTABLE LENS.—Dr. Cuoco, of Paris, has invented a lens of variable focus, in which the pressure of transparent liquid is made to alter the curvature of the flat faces of a cylindrical cell of brass closed with thin glass discs; the pressure can be regulated by a manometer gauge to any required degree within the limits of working.

HIGHT OF THE AURORA BOREALIS.—Drs. De La Rue and Muller determine the height at which the aurora borealis has its greatest brilliancy at about 38 miles; at a height of 81 miles the light is pale and faint, and at 124 miles above the earth's surface no electric discharge can take place to produce the phenomenon.

IMPROVED ELECTRIC BATTERY.—M. Reynier has introduced a new battery which is claimed to possess twice the electro motive force of the ordinary Bunsen couple; a solution of caustic soda is substituted for nitric acid, and the "porous" cell is constructed of parchment paper.

A Trans-Neptunian Planet.

In the *American Journal of Science*, Mr. D. P. Todd, of the "Nautical Almanac" office, Washington, details the efforts made by him to discover a trans-Neptunian planet. In 1874 he began a speculative search for such a planet, the presence of which has been suspected by earlier astronomers of eminence, and in October, 1877, he reached the following as a result of his inquiry: The longitude at that time would be approximately 170°; mean distance from the sun, 52; period of evolution about the sun, 375 years; stellar magnitude, about 13, and inclination of orbit to elliptic, 1° 24'. The practical search with the 26-inch telescope at the Naval Observatory, begun on November 3, 1877, and ended March 6, 1878, was unsuccessful. It was necessarily confined to narrow limits, but it was thorough so far as it went. Being unsuccessful, Mr. Todd did not see any benefit in publishing the negative result. He adds, however: "The matter now assumes a very different aspect; the publication of a recent memoir 'On Comets and Ultra-Neptunian Planets,' by Prof. George Forbes, of Glasgow, assigns, by a method of investigation entirely independent of my own, a position to a possible trans-Neptunian planet which may be regarded as in exact coincidence with that which I have deduced. Should a careful and protracted search of the region adjacent to the indicated longitude prove unavailing, no more certain test of the existence of a trans-Neptunian planet admits of application within the next few years than that of telescopic search of a limited zone extending entirely around the heavens—a search which I have been hoping, for more than two years past, for an opportunity to undertake, but which I see no present prospect of realizing."

A NATIVE ALLOY OF SILVER AND COPPER.—S. B. Wright, M. E., of Detroit, in a letter to the *Engineering and Mining Journal*, reports the discovery of a native alloy of silver and copper, in mineral sent to the Detroit and Lake Superior Copper Co. to be smelted. In appearance after cutting, it bears a close resemblance to a light-colored brass, although on the surface it has the color of silver. Two samples, whose specific gravity were taken, gave respectively 9.9432 and 9.3300. In composition he found the percentage of silver to vary from 53% to 75%, the remainder being made up of copper, with traces of iron and sulphur. Under a strong magnifying glass, the samples show a perfectly homogeneous structure, no wave lines or anything to indicate a mechanical combination being visible. He also adds: "As I have never known or heard of such an alloy being found, I was at first extremely doubtful about it, and submitted samples to a Mr. Marsh, a chemist, formerly connected with these works, who corroborated my views." Mr. Wright hopes soon to be able to give further facts in regard to this interesting discovery.

THE ORIGIN OF THE DIAMOND.—M. J. A. Roorda Smit has in the *Archives Néerlandaises des Sciences Exactes* a paper on the diamond mines of South Africa. He states that the diamond is found in a primitive gangue of volcanic origin, the presence of a double carboniferous silicate being a characteristic of these mines, which he regards as extinct craters of volcanoes. His hypothesis is that the diamond is of Plutonic origin, formed at the expense of organic matter under the influence of great pressure and at a high temperature. The recent artificial production of the diamond appears to confirm this view. M. Meunier states in the *Comptes Rendus* that he has produced crystals of spinel, and he believes periclase and corundum, by the action of steam on the chloride of aluminium in presence of magnesium at a red heat.

WAVES OF COLD.—Mr. R. G. Jenkins, F. R. A. S., has attempted to show a very remarkable effect of the planet Venus upon the earth. Many years ago the present Astronomer Royal proved that the disturbing effect of this planet was so great that the earth was materially pulled out of its orbit. Mr. Jenkins shows that it is to this disturbing action we must look for an explanation of the cold waves, which occur, on an average, every eight years—as in 1829, 1837, 1845, 1855, 1863, 1871, 1879—and that for the next 40 years the temperature will be below the average, as it has during the last 40 years been above the average. In regard to high temperatures, he states that for the last 50 years a heat wave has been observed to pass over the earth every 12 years, nearly contemporaneous with the arrival of the planet Jupiter at its perihelion, and that we are on the eve of the next heat wave.

TELEPHONIC EFFECTS, according to M. Ader, result from the shock of magnetic bodies. He says that any mechanical action that disturbs the molecular condition of a magnet core develops, when the core suddenly regains equilibrium, an electric current capable of affecting the telephone.

ACTION OF OZONE ON SILVER.—Under the action of ozone, silver quickly assumes a coat of black oxide, but gold and platinum remain unaffected. Mercury is superficially oxidized by ozone.

MINING SUMMARY.

THE MANZANITA DITCH.—Work on the new ditch of the Manzanita mining company is being pushed ahead at various points with a force of about 60 men, mostly Chinese, and it is expected everything will be in readiness to turn water on by Nov. 10th. The ditch will be used to convey

THE race for the Lancaster cup was won by Dresden China, Eideweiss second, Schoolboy third.

* THE project of securing the *Great Eastern* to run between London, New Orleans and Galveston, to take our cotton and other products and bring back emigrants, is in a fair way of being fully established.

surplus water in winter from Deer creek, 1 mile below Scott's flat, to the Manzanita mine, in the northern outcrops of this valley, having a total length of 2 1/2 miles, dimensions will be 8 1/2 ft at the bottom, 2 1/2 ft at the top, and 2 1/2 ft deep. The cost of construction is estimated at a little less than \$10,000. The owners are building the upper end.

BEAR RIVER NEWS ITEMS.—The American copper mine, at Spencerille, is producing cement at the rate of 300 lbs a day. Freight received by rail at the Wheatland depot, during the past week, amounted to \$25,346. Freight forwarded from that station, \$21,097.84, of which \$9,000.00 was copper cement from the Spencerille copper mine. Shipments of potatoes were very small, only 4,705 lbs. Total freight to and from this station required some 30 cars during the week for its transportation.

WORK ON THE MAIN DITCH.—It is now expected that the South Yuba water and mining company will begin enlarging their main ditch about Oct. 1st. Among the repairs already begun on the line is the construction of a flume across the North Fork of Steep Hollow. This flume is to be 60 ft high, and between 700 and 900 ft in length. This job will not be completed till the latter part of the month, but in the meantime, the water will be run as usual through the old flume.

THE RIVER.—The Hartung & Hetherington, at Scott's flat, will this winter run a 500-ft tunnel, by which to work their gravel claim to better advantage. A number of good clean-ups have been made by them this season.

A LARGE shipment of bullion was brought down yesterday from the North Bullionfield hydraulic mine and sent to the bay through Wells, Fargo & Co.

It is expected that some Eastern capitalists will arrive here next month for the purpose of examining the Potol quartz mine on Gold flat with a view of purchasing it.

The South Yuba water and mining company, of New York, whose property is situated in Nevada and Placer counties, have just issued a very complete prospectus of their possessions.

YOT BAR.—The Bird's-eye Creek or English company is making good clean-ups in their claims at Brown's hill. They are fitting up their claims at Red Box, as they propose to operate there also next winter. The lumber for building flumes is already on the ground. The mines at Lowell and Henington hills are said to be looking well. The Swamp Angel will in a few days begin taking out gravel through their new tunnel.

A GOOD YIELD.—Saturday a clean-up was made from 4 tons of ore extracted from Ed. Moore's mine, on Little Deer creek, and \$40 a ton was realized in free gold. The sulphurates, of which there were a liberal quantity, will, it is believed, pay in the neighborhood of \$100 a ton.

THE CHIRONAX.—Thirty-eight tons of ore are on the dump at the Chironax lead, Canada hill, and a crushing will be made soon. The ore continues to look as well as it did last July, when a lot of it was milled and 6 tons paid \$150 a ton, the remainder averaging \$40.

A FINE BAR.—Herald, Sept. 18: An armed guard from the North Bullionfield mine, yesterday brought to town a gold bar for shipment to the bay. The value of the treasure would probably reach the sum of \$18,000 or \$19,000.

NEW MINING ENTERPRISE.—Grass Valley Union. The machinery of the Oakland mine ranch, on Allison ranch, on Wolf creek, is to be removed to the Penobscot mine, on Church ravine, just north of the Gold Hill mine, and a shaft sunk to the depth of 200 ft.

PLACER.

LAST CHANCE AND DEADWOOD.—*Cor. Argus*, Sept. 18: Last Chance and Deadwood, two old mining camps, formerly prosperous, but of late years generally regarded as being "played out," are beginning to show unmistakable signs of returning prosperity. In both camps a number of claims long since abandoned except by the representative, who was expected to make annual pilgrimages to their localities, are now being got in readiness for work. Some are already being worked. Bishop's hydraulic claim at Last Chance, has been blessed this season with a good run; yielding a rich reward. The Caledonia has been reported to be producing well. The El Dorado is paying out the just reward of energy and pluck. The El Dorado is running for the back or Morning Star channel, which they hope soon to reach. The Root Hog company will soon get their new tunnel into the channel, and it has cost the company about \$10,000. They know that as soon as they get into there they will get good pay; they could not work it heretofore owing to a lack of proper drainage. At Deadwood every claim being worked is paying, I believe, and paying well.

HUMBOLDT CANYON AND DAMASCUS.—The town of Damascus is now more prosperous than it has been for the past two or three years, from the fact that the mines are all paying better than for that period of time. In the immediate vicinity of Damascus all the mines are gravel drift mines and are paying quite well, generally, this season. Lower down the American river several quite extensive drifts are being prospected and worked. The Giant Gap gravel drift mine has a tunnel in over 800 ft, and are still pushing ahead. They expect to strike the main gravel lead in a few more hundred ft. The Union quartz mine, formerly known as the Pioneer, is being worked and good prospects have been found. This mine was worked many years ago when large quantities of gold were taken out, but it was thought all the paying rock had been taken out and the mine was shut down. No work has been done for a great many years. The Poole quartz mine is getting better all the time. The 5-stamp mill is to be enlarged by the addition of 10 more stamps. The last run made paid \$30 per ton above all expenses. A large number of new claims are taken and are being prospected. It is thought a quartz boom will soon be had over in Humboldt canyon.

PLUMAS.

POORMAN'S CREEK.—*Quincy National*, Sept. 18: The mining interests are on the boom. A remarkably rich strike was made on the head of Nelson last week; many claims were staked off, and the end is not yet. D. R. Thomas has cleaned up his lower claims for the season, and has had in his hands 200 pounds of the yellow stuff as the result. For the time he has run it has paid well. He has a good property here, and Poorman's will again boom up. This is the region to prospect in, and if done with system and energy, is sure to prove remunerative. This is my prophecy, though I am not a prospector and have no mines to sell. Wish I had. The Kellys are hopeful of developing good mines, and they deserve it.

QUARTZ MILLS.—Mr. E. A. Henth, who recently returned from below, informs us that he will soon put up 2 quartz crushers on his mine at Argentine. The mills are something new, "the Huntington quartz mill," and are said to be very successful. Henth thinks the 2 will crush from 24 to 30 tons of rock per day. The mills will soon be shipped, and put in running order as soon as possible.

SIERRA.

RICH STRIKE.—*Mountain Messenger*, Sept. 18: Some Portuguese have discovered very rich gravel claims at the junction of Spencer lake and head of the Middle fork, 15 miles northeast of Downville. Coarse gold is found in abundance, some nuggets being valued at from \$7 to \$10.

QUARTZ MILL.—The owners of the Forest Quartz mill, located at Downville, have contracted for and will soon have on the way here a quartz mill capable of crushing 20 tons of quartz per day. It is the intention of these gentlemen to have the work vigorously. The mill will be located at the lower end of Durgan flat and will be run by water.

NOTE.—Wallace & Co.'s hydraulic mine, located 2 1/2 miles above Downville at Sweetwater ranch on the North fork, has a good prospecting claim, which may yield well next season. Brown & Ward shipped them 200 ft of 12-inch pipe this week.

TRINITY.

COFFEE CREEK.—*Trinity Journal*, Sept. 18: From Mr. George Williams of Trinity Center we learn that the Nash Deep Gravel M. Co. has commenced operations on Coffee creek and are making things lively in that section. A number of men are at work on a trail to their mines and the machinery for a saw-mill, now at Carr's ranch, will be

packed in as soon as the trail is built. The company owns a large body of land, have plenty of water and prospects for gold and silver are said to be very promising.

NEW RIVER.—We occasionally hear faint rumors about work being done by the New River Hydraulic Co., who are digging a ditch and building a flume to Hawkins bar. As all their material and most of their workmen were brought by way of Eureka, we know but little about what they are doing.

TUOLUMNE.

WATER CO.—*Tuolumne Independent*, Sept. 15: A crew has gone up on the line of the Tuol. Co. Water Co.'s works to put the ditches in order, make the necessary fall repairs to flumes and reservoirs and to get out timber, etc.

A suspension bridge flume will be put in at Long camp, about 40 ft high and 80 ft long, at a place where it is difficult to keep supports from sliding out. They will get out the timber now, and put the bridge in place before the rains. A 400-ft boom will also be placed in the Strawberry reservoir to keep descending debris from injuring the dam.

NOTE. There will be a continuous run of water this year in the Tuolumne Co. Water Co.'s canals, as the supply is said to be abundant. While putting in the suspension bridge at Long camp, however, which may take a week, the water will have to be shut off.

NEVADA.

WASHOE DISTRICT.

OVERMAN.—The Virginia City *Enterprise*, Sept. 21st, contains the following statement: Winze from 1000 level has been extended 30 ft; total depth, 133 ft. Incline upraise has been extended 30 ft. Forman shaft has been sunk and timbered 20 ft; total depth, 1,420 ft. Have also put the standing lift-pump in and started it up.

CALADONIA.—Pumps have been run an average of 18 1/2 hours per day. Consumed 7 2/7 cords of wood per day. Forman shaft has been sunk and timbered 20 ft; total depth, 1,420 ft. Have put in the standing lift-pump and started it up.

SAVAGE.—We have retimbered and repaired 12 ft of the main shaft and 10 ft of the 10th station, and have advanced the northwest drift on 10th level a distance of 25 ft. Have pumped once each day from 3 1/2 to 4 hours.

C. N. S. SHAFT.—Have cut out the pump station on the 2400 level 5 1/2 feet deep and put in 6 sets of timbers. The coping stones are on the foundations for the pumping engine, and workmen are dressing them down.

EX-HUQUE.—No work has been done in the mine since the late accident in the shaft of the Con. Imperial.

G. & C. AND B. & S. SHAFT.—Have sunk and timbered the shaft during the past week 30 ft; total depth, 1,610 ft.

CON. IMPERIAL.—The crosscut east of the south winze station, 2310 level, is 41 ft; face in porphyry.

AURORA DISTRICT.

REAL DEL MONTE.—*Esmeralda Herald*, Sept. 11: During the past week all operations have been centered in the sinking of main shaft, which has been sunk and timbered a distance of 18 ft, making the present total depth 74 ft. There is no change to report in the character of ground passed through, the formation being very kindly.

A station set has been put in at the 750 level.

AURORA CON.—Work is progressing in a very satisfactory manner on this property, the tunnel having been advanced 22 ft during the past week, making a total of 67 ft. The formation in the last 14 ft run is hard country rock, with some vein matter and soft clay.

LYNCE.—Everything is looking fine in this mine, with better prospects every foot advanced. The incline is now down 50 ft, the ledge at the bottom 6 ft wide, pay rock all through. The present contract will probably be finished this week and another contract let, but only a small one, as Mr. Booker says that if the rock keeps improving as they descend, the mine will be present day a bonanza.

The ore taken out will apply pay for the mill and leave quite a little sack for the fortunate owners.

BRISTOL DISTRICT.

HUTCHINSON.—*Pioche Record*, Sept. 14: Owing to the making of a pump, the Bristol S. M. Co.'s mill had to hang stamps for a few days, but is again crushing and working through 14 tons of ore per day. All parties who have seen the mill in operation pronounce it the best and most complete construction of the kind they have seen.

The iron mine is steadily improving and shipping about 10 tons of ore per day. The refinery had to close down temporarily, owing to the want of pearlash, but has since been working again.

The hill-side furnace is still turning out bullion in large quantities; a great number of tons on the dump awaiting shipment, but owing to the scarcity of teams is accumulating very fast.

ONE.—*Pioche Record*, Sept. 11: This mine, the property of the Bristol company, is developing first rate. The men working in the back part of the old cave, where ore was first struck, have encountered a fine vein of ore. It is thought that there is a chain of ore caves at this point.

In the upraise, in a different portion of the mine, a large quantity of ore is being extracted. The Bristol company now has a large force of miners employed.

EUREKA DISTRICT.

PHENIX.—*Sentinel*, Sept. 12: The lessees of this mine are shipping ore, and have now some 20 tons on the dump. It is alongside of the K. K. Eureka Con. and Jackson mines, and this fact is greatly in favor of the mine.

BUNSTON.—*Esmeralda Herald*, Sept. 11: The mine is now taking out some very fine ore, if the sample we saw was an average. All the mining properties on the southeast side of Old Prospect are booming up, and considerable capital is backing the faith of the owners.

RICHMOND CON.—*London Mining Journal*, Aug. 28: The usual telegram from the mines at Eureka, Nevada, states that the week's run was \$90,000 from 1,180 tons of ore. During the week the refining produced 400 bars of the value of \$15,000. One day was lost through the fire. The manager reports that the winze sinking below the 200 from the cave is down 20 ft, the bottom of which is in ore. He has no doubt they will make a connection in ore from this winze to No. 15 chamber east. The 600, north from No. 14 chute, has been drifted 16 ft in ledge matter, with bunches of galena. The present end is in ledge matter, but not so much galena as there was; still, the indications are good for striking ore.

REY-DUNDERBERG.—The progress of the company's mining operations continues to be highly satisfactory. The temporary confusion incident to the fire at Eureka will account for the meager amount of work reported in the weekly telegram. The smelter selected by the company sails for America to-day.

GOLD MOUNTAIN DISTRICT.

GOOD PROSPECTS.—*Esmeralda Herald*, Sept. 11: Late advices from this district, situated about 20 miles from Lida valley, state that mining prospects are excellent. The State Line mine is situated in this district, and yields a lot of very rich free-milling ore containing nothing but gold. The Oriental is also a good property, the ore being gold and silver and the best going as high as \$800 to the ton. The Rattlesnake has gone down on the ledge to a depth of 78 ft. Vein 5 ft wide, and yields ore that will average \$80 per ton. With this showing there is but little room for doubt that they will have lively times at Gold Mountain in the near future.

LEWIS DISTRICT.

SALT.—*Silver State*, Sept. 25: Walter Schmidt, of the Desert Crystal Salt Works, is building a salt mill at Eattle Mountain, of a capacity of 15 tons a day. It is necessary that the salt should be ground for the roasting furnaces at the mills in Lewis district, and he is building the mill for their accommodation and to supply the market with table, dairy and meat salt.

LINGTON DISTRICT.

IMPORTANT DISCOVERY.—*Salt Lake Tribune*, Sept. 18: This new district, in White Pine county, Nev., is 250

miles southwest of Salt Lake City, and is attracting great attention. The region has been known for years, but it was difficult of access, and now that the Utah Southern Extension has been completed, it will be brought within reach of capital. The only outlet for the district is through Utah. The ore is a high-grade millable quartz, and the ledge, which is from 3 to 8 ft wide, will run from 60 to 1,500 ounces, silver, and some gold, per ton. Unlike the majority of the Nevada camps, Lexington district is heavily timbered, with abundance of water and feed for cattle.

PHILADELPHIA DISTRICT.

BELMONT.—*Belmont Courier*, Sept. 11th, contains this official letter: Will extract about 10 tons first-class ore the present week that will mill about \$100 per ton, and about 20 tons of \$80-ore. Ore stops above 500 level, on the north side of the Hogan upraise, are showing a very fair quantity of ore, and are being prospecting. There are at present are in drift going south from the top of the Hogan raise; also 150 ft south of Hogan raise, above No. 4 raise, where we have found what appears to be a fine body of ore, but cannot work either of those points to any advantage until we put in ore chutes and do some dead work, which I will do next week. Then I can increase the production of ore.

PIOCHE DISTRICT.

BULLIONVILLE EXTENSION.—*Pioche Record*, Sept. 11: There has been an extension of the Bullionville mine located by Dr. Nichols and J. C. Henderson & Co. A contract was let to sink a shaft 50 ft, and is down about 30 ft. The ground is soft and easily worked.

SILVER CANYON DISTRICT.

SALE.—*Hamilton News*, Sept. 16: Mr. W. B. Lawler, of Silver Canyon, last Friday consummated the sale of some valuable mines in that district to Dr. Brooks, for a prospecting and mining interest for the prospecting was \$20,000. The most promising of the series sold were the Sadie L. and Blue Bell mines. The Sadie L. is stripped for 700 ft, and an incline is sunk on the ore for a distance of 112 ft. The average of the ore body is 5 ft. The company is erecting a 10-stamp mill, with sufficient capacity for an increase of 10 more stamps, which will be completed in about 30 days. Silver Canyon has a business-like appearance, and is sure to make a good and substantial camp. There are about 60 men employed in the mines at present.

SPANISH BELT DISTRICT.

BARCELONA.—*Belmont Courier*, Sept. 11th, gives the last official letter: Since my last report we have made connection in north upraise with air shaft, but will take a few days to complete it; will be obliged to timber up so it will be in good order. I am stopping out good ore from north level and will ship as fast as possible to Eureka. North level shows a well-defined ledge 4 ft wide and very solid. Will push it ahead as fast as possible through a splendid body of pay ore.

TYBO DISTRICT.

BULLION.—*Belmont Courier*, Sept. 14: The output of bullion from Tybo for the month of August was something over \$19,700, one of the best monthly showings in the history of the mine.

WHITE PINE DISTRICT.

PROSPECTS.—*Eureka Sentinel*, Sept. 17: A gentleman who seems to be well posted on White Pine affairs, does not express himself very enthusiastically of the future boom in the Hamilton section of the county. He says there is considerable prospecting going on all around the mountain and Treasure hill, in the tunnels and everywhere. Should any strike be made, then would come life. As matters now move along, the Eberhardt mill is grinding away on tailings. Their supply will run out in about 3 months longer, and if the company cannot secure those belonging to the South Aurora mill, and there should be no ore to treat, the stamps would have to rust out. The old White Pines dig with a dogged determination, and if there is any bonanza in that section it must and will be shown up.

ARIZONA.

HARSHAW DISTRICT.—*Bullion*, Sept. 11: The boys on the Red Top ledge, the longest well-defined ledge in the district, are doing good work. On the Maryland a body of \$200 ore has been struck. The contract for the 60-ft shaft on the Silver Bill, in Washington camp, has been completed, and a new contract for 125 ft of sinking and drifting has been let. Work is progressing steadily on the Alta mine, the rich strike at 140 ft greatly encouraging the owners. Mr. E. C. Richardson, on Saturday last, let a contract for work on the Harshaw mine, one for shaft 100 ft deep, and another for a tunnel to cut the ledge. From the Nevada standpoint, the town of La Nora is a lively and prosperous place, quarrels and fights being almost of daily occurrence. But these alone do not make it a success, for in fact the place is improving rapidly in business and population, and has fine prospects ahead. The Harshaw smelters are rapidly approaching completion, and will be in full blast some time during the month of October. An accident occurred to the rock-breaker at the Harshaw mill, and it is temporarily laid up for repairs.

GLOBE DISTRICT.—*Silver Belt*, Sept. 11: We have authority for stating that M. A. Baldwin has procured a lease of the old Globe mine. A force of workmen is already at work. This mine has produced some excellent ore, but has been so mismanaged that it grew into disaster.

SILVER NUOGET.—We have been informed by good authority that the north shaft of this mine has cut the vein 60 ft below the first level, and that the same rich ore was found. This being some distance below the water level is conclusive evidence that the vein is permanent, and that the ore continues.

MACK MORRIS.—They have made important developments in the 100 level of this mine. The crosscut from the winze shaft cut the vein on the 100 level on Friday, and it shows a 4 ft thick of fine ore. From the crosscut, the ore leads east and west, and establishes the fact that the Mack Morris is a bonanza mine.

NOTE. The material which was wanted for the completion of the Townsend mill has all arrived, and it will soon be busy pounding ore. There are 300 tons of ore on the dump. It is expected that the Golden Eagle mill will be running by the 1st of October. They will commence to crush ore in the Isabella mill in a few weeks.

DOS CABEZAS MOUNTAIN.—*Cor.*, The *Esmeralda Herald*, Sept. 5: The town of Dos Cabezas, or "Two heads," is delightfully situated at the foot of the mountain of the same name. The mines, as they are called in the district, are really nothing but prospects, but they are flattering ones. The hopes of the district are centered on the great ledge fronting the town and lying on the south side of the Dos Cabezas mountain. The ledge is about 50 ft wide, and crops out fully 100 ft from the mountain. The ledge is 1,500 ft long, and they all show rich mineral.

COLORADO.

GULPIN COUNTY.—*Register-Call*, Sept. 17: Connection has been made by drift with the east shaft on the Egyptian ledge, Quartz hill, and the work of sinking the main shaft has been resumed. The mine now has plenty of ventilation. Levels are to be commenced below the 100-ft station. In the bottom of the main shaft, a small but rich vein of peacock ore has been struck.

HAYES & WARD.—The owners of this ledge, at Missouri City, are sinking the main shaft, and have attained a depth of 64 ft. The mill ore is yielding from 4 to 5 ounces gold per cord.

KENT COUNTY LEAD.—Another rich strike of a wide vein of mill dirt and smelting iron is reported in the 700 level of this ledge, in Nevada district. This level is in a distance of 500 ft from the main shaft, the present heading of which shows from 4 to 6 ft of pay ore. The same may be said of the back stops which are being worked.

IDAHO.

WALKER DISTRICT.—*Idaho World*, Sept. 17: Joe Donasters and Joe Pitzer have gone up to Walker district, near Banner, to work on the ledge recently discovered by them. It carries both gold and silver, and is 12 ft wide. The vein will be tapped by a tunnel. Quite a number of new discoveries have been made this summer in the vicinity of Banner, and the surface prospects in all of them are very encouraging.

BANNER DISTRICT.—Times are lively here now. The Elmira Co. has about 100 men employed. Their shaft has reached a depth of 160 ft. When a depth of 200 ft is attained a cross-cut that will tap the vein 120 ft lower than ever, will be run to the ledge. Work is still progressing in the old Crown Point tunnel. The mill is running at full blast. Have had considerable trouble with the rock breaker, but everything is lovely now. Under the management of Col. John Brown, President, and Major McDowell, Superintendent, the Elmira Co. has made a success. They are the right men in the right place. The laminit is looking as well as ever, and the boys are taking out rock. The town of Banner will soon be as large as Idaho City. It is building both ways—up and down the gulch.

GRANITE CREEK.—*Idaho World*, Sept. 10: The Chinese company that bought the mining ground of the Danekin Bros., on Granite creek, about 2 years ago, have 70 men employed. Ground sluicing was carried on this season until a short time ago, when water slackened, since which time they have been sluicing up. Five long strings of sluices are used, with 4 men at each string. The rest of the men are employed in the blacksmith shop and at other work. The claims will be run until water freezes. The ground pays well.

NOTE.—Between 300 and 400 men are at work on Bay-horse and Kinnikinnick. The 2 furnaces to be put up in these districts this fall will smelt 45 or 50 tons of ore per day. The men at work for use companies get their greenbacks every Saturday night.

MONTANA.

FOR DEEPER DEVELOPMENT.—*Butte Miner*, Sept. 16: While in the East Mr. John Caplice, manager of the Northwestern mining company, at Philipsburg, purchased for the Trout mine a Knowles vertical sinking pump, with which it is his intention to sink on the Trout to a depth of 200 ft below what is at present the lowest level. Mr. Caplice succeeded in having his lease of the mine extended, and the new Algonquin mine is making a most gratifying success in its reduction of Trout ore.

THE HOLTZ MINE.—F. B. Dunn brought in, yesterday, from the Hallbeck mill, Elkhorn district, Jefferson county, 5 bars, weighing 210 lbs offhullion, valued at \$3,255. This was the result of 1 run in the Hallbeck mill of ore taken from the Holtz ledge, owned by Hallbeck & Black. The Holtz mine is a big one. It is opened by a main shaft to a depth of 225 ft. The ore vein is wide, averaging over 30 ft. Of this 30-ft vein fully 4 ft assays 100 ounces per ton. The last run of the mill cleaned up 73%.

ALICE.—Under the superintendence of W. E. Hall, the property is being developed with the usual systematic energy. The crosscut north from the 700-ft station is delayed for a few days, pending the arrival of 2 mammoth pumps new in transit.

NOTE.—On the dump of the west shaft is 500 tons of ore, and extraction has been suspended until the mill catches up, when a further supply will be taken from the almost unlimited amount opened up between the 1st and 2d levels. The new double-compartment shaft has attained a depth of 120 ft.

SUNNYSIDE.—After lying idle for several months, operations have been resumed under bond. In the east drift of the mine, the vein was supposed to be 10 ft wide, and a little prospecting developed a 6-ft vein of fair-grade milling ore, compact and clean, and giving evidence of improvement.

DIAMOND.—The shaft is 80 ft deep. The ore continues to be of somewhat low grade, but is extracted in sufficient quantities to pay well for reduction.

NEW MEXICO.

MINING SALE.—*New Mexico Press*, Sept. 16: Mr. I. W. England and Mr. Frank Hoxie, of New York, last week completed the purchase of the Rachel Creek and Virginia mines, in El Cerezo district. They bought the interest of the Messrs. Irwin, the discoverers, and also the title of the Maxwell Land Grant Company, and competent judges say that they have secured a most valuable property at a very moderate price. Col. Bergmann has been placed in charge of the development of the mine, and Messrs. England & Hoxie are to put in machinery at once.

MR. CHAS. S. WELLS was in from Cimarronito district on Monday. Mr. Wells showed us assays made from the Contention mine, on Red Jacket hill, by Mr. G. Nixon, of Chicago, that ran as follows, almost entirely gold: \$139.50, \$322.45, \$28.94 and \$109.80.

TEAR. is a great deal of mining excitement in Taos county, and there will be a large amount of litigation arising about titles.

LAKE VALLEY.—*Grant County Herald*, Sept. 18: Much excitement prevails in the Lake Valley district. E. B. Learned, who arrived there last Thursday, informs us that Cox & McLean had just handed their Emporia mine for \$30,000 and their Strichy mine for \$10,000. Dan Green and Jim Swartz had been offered \$1,500 for one of their mines, but refused to take less than \$5,000. Jno. A. Miller's claims are considered among the best in the camp. Mr. Learned himself, while at Hilleborough, and before hearing of the boom, had sold a claim for \$350, and immediately afterwards ascertained that the party purchasing had been offered \$4,000 to secure the property. About 30 miners are at work, and more are constantly arriving.

UTAH.

DRY CANYON MINES.—*Salt Lake Tribune*, Sept. 14: The mining boom has not fairly settled on Dry canyon yet. A few of the old mines are being worked, but not to any extent. Mayberry & Gibbons are doing well on their lease in the upper workings of the Hidden Treasure, while Jim Gould keeps a sharp force prospecting in the depths. Bears & Neader are running 2 jiggers on the Kearsarge dump and are reported doing well—at least well enough to hold on to what they've got. Dick Gundry has 5 or 6 men on the old Queen of the Hills, which force will be added to from time to time. Outside of the few small prospects, on which assessment work is being done, Dry canyon is said to be very dull; but bright days are yet in store for this rich camp.

SILVER REEF.—*Silver Reef Miner*, Sept. 12: Louis Hassel and Henry Freudensthal, two of the chloridors at present working on the Thompson & McNally, dropped a specimen of ore into the Miller office last week that did our eyes good to gaze upon. At the first glance one might suppose it to be a chip off an ordinary piece of ore, but a closer examination would show a crust of horn silver fully an eighth of an inch thick, which covers the surface of the whole specimen.

UTAH CANYON.—*American Fork cor.* Salt Lake *Tribune*, Sept. 0: This camp has been neglected for several years, but is now receiving attention from capitalists. The mountains are rugged, and the veins are generally found in the crevices. The Silver Bell, for instance, a mine that has about 20 ft of \$85 ore, and it is visited by fewer parties in camp than almost any ordinary location, and only because it is at the highest stretch of mountain that lies in the camp. The Pittsburgh mine also is at an extremely high altitude, and so with the generality of good mining properties in the camp known in Utah for years.

PERREBURG.—This is a mine of rather low grade. As if to make up for the quality, nature has very kindly allowed the owners with but little work to place thousands of tons in sight. It is now shipping 15 tons per day to the Morgau smelter.

SILVER BELL.—This mine, without doubt, is the chief work of the camp. It ships several tons almost daily, and will keep up a continuous shipment but for the fact that it is under hand away up in the neighborhood

The Moon's Force.

After getting somewhat accustomed to the greatness and strength of a bar of solid steel 16½ ft. square, imagine one which is one mile square, 5,280 ft. wide and as many thick. If it lay on the ground near the Catekill mountain, its upper surface would overtop their highest summit by more than 1,000 ft. It would be equal to 102,400 such monster bars as the last. Its lifting power would be nearly 240,869,000,000 tons. The mind is utterly unable to grasp such figures. The whole globe contains 1,200,000,000 inhabitants. If each man, woman and child could pull with a force of 100 lbs.—a large estimate—to move such a weight would require the united efforts of the inhabitants of 2,000 such worlds as this.

As I shall have frequent occasion to speak of the load which such a bar could sustain, I shall, for convenience, call it in round numbers 240,000,000,000 tons, neglecting the other figures, because the number is so inconceivably great that taking from it a billion or so of tons will alter the result less than one-half of 1%. This bar is to be the unit of measure, which I shall for the present employ, and with its help I shall attempt to give some idea of the influence of the sun in holding the system together, and of the attraction exerted by the planets upon our earth, and by the earth upon the moon; and, lastly, by the fixed stars upon the sun and upon each other.

We begin with the moon because it is nearest to us, and, with the exception of the sun, is to us the most important of all the heavenly bodies.

If a half dozen persons were asked how large the moon appears, they would give as many different replies: "The size of a cart wheel," "Twelve inches across," "The size of a dining plate," "As big as a man's head," etc. Probably no one would mention a smaller measure, yet a cherry held at arm's length much more than covers its disk. It is difficult to believe that so small a body exerts any considerable influence on the earth which seems so immensely larger. It is easy to admit that the earth holds the moon in its orbit; but that to do this, to bend its course into a nearly circular orbit, requires any great outlay of force, is not so clear. Our credulity would be taxed were we asked to believe that the moon in its efforts to move in a straight line would break away, although held by a bar of steel one ft. square, for that means a force able to lift nearly 9,000 tons. An astronomer would grant it, making first a mental calculation to see if he was justified in doing so; but even he would hesitate, and perhaps would deny that it was possible the moon could pull asunder one of those great unit bars one mile square, and equal to more than 27,000,000 bars each one ft. square.

But he would have no hesitation in saying "Impossible!" if told that, rather than change its course from a straight line to its present curve, our willful little satellite would snap like pack-thread not one, nor two, nor three of those unit bars, but the united strength of 10,000—or, in other words, one gigantic bar whose section is 100 miles square. Yet more than eight such bars, or more precisely, 87,500 unit bars, would but barely deflect the moon into its present path*.

* The non-astronomical reader may, perhaps, need to be reminded that the moon does not move easily and naturally in a circle—or ellipse—but that its path, if left to itself, would be a straight line—a tangent to its orbit. Consequently, the moon requires to be forced into a curve.

—Popular Science Monthly.

THE LAW OF ENTAIL.—Much apprehension exists in this country as to the present powers of entail in England. There is no such thing as a law of primogeniture, except in so far that if a man die intestate his real estate would pass to his eldest son, except in Kent, where it would be divided among all his sons. Up to the close of the last century, the power of entail was illimitable. It was curtailed in consequence of the extraordinary will made by a merchant named Thellueson, of Swiss origin, who accumulated a vast fortune in London, partly by buying up jewels from French emigrants at the time of the great revolution. Mr. Thellueson intended his money to accumulate until it would have reached about \$700,000,000. The government deeming it undesirable that any subject should possess wealth so colossal, introduced a bill limiting entail to living persons and 21 years afterward. This is not much greater than the power of entail in New York, and almost identical with that in Massachusetts. Many estates in and around New York—the Lefferts, Rhinelanders, for example, are entailed. In England hundreds of great properties are completely unentailed, and it is purely the custom, not the law, of the country which will cause them to be transmitted to the eldest son. Men who are very liberal in politics favor the custom, because they think it keeps up the position of a family, and that were an estate divided up in the next generation none would be better for such division. It is not generally understood here that the law in England permits a man to leave his property precisely as he pleases, and that a duke can leave all to his footman. The great estates, for instance, of the duke of Hamilton, premier duke of Scotland, were, up to the time of his marriage, absolutely unentailed. This came out in some law proceedings. —Springfield Republican.

Indian Grass or Wood Grass.

Our engraving shows a grass which will be recognized by many of our readers who hail from the prairie States, where it figures quite largely in the native pasture. Botanically, it is a sorghum (*Sorghum nutans*), and it is tall-growing in its habit, the stalks being from three to four ft. high, in favorable locations.

In order to show how grasses may vary in chemical composition and thus differ widely in economic value, we place side by side the proximate analysis of *Sorghum nutans* and *Sorghum Halapense* (green valley grass):

	<i>Sorghum Nutans.</i>	<i>Sorghum Halapense.</i>
Oil.....	1.57	2.25
Wax.....	.10	.61
Sugars.....	7.27	7.37
Gum, etc.....	3.75	5.14
Cellulose.....	36.70	25.15
Amylaceous do.....	27.25	25.87
Alkali extract.....	14.44	15.58
Albuminoids.....	3.29	13.18
Ash.....	5.63	4.65

The analyses were made by Dr. Peter Collier,

INDIAN GRASS OR WOOD GRASS—*Sorghum Nutans*.

chemist of the United States Department of Agriculture. The superior richness of the *S. Halapense* in oil, sugars and its notable increase of albuminoids, are plain evidence of its great comparative value. It has more gum also, which there is some reason to believe is convertible into sugar in the animal digestion. On the other hand the *Sorghum Halapense* has much less cellulose, which is indigestible and worthless. We gave an engraving of *Sorghum Halapense* in our issue of March 27, 1880, and it is interesting to compare their appearance in connection with this statement of their comparative composition.

Sorghum nutans has not been generally considered of much value except as one of the grasses in the native pasture, although if cut early the hay is nutritious. The main trouble with it is that it grows rather scantily and does not cover the ground well.

The stalks are smooth, hollow and straight, and have at the top a narrow panicle of handsome straw-colored or brownish flowers, which are rather drooping when the seed is formed.

There is one mining district in this country called "Tin Cup," and another one has been named "Old Hat."

A GIGANTIC MINING PROPERTY.—The property of the San Pedro and Canyon del Agua M. Co., located in New Mexico, of which it was reported that Gen. Grant had been elected president, is very fully described in the *New Mexican*, published at Santa Fe. According to that journal, the property embraces 36,000 acres, covered with pinon timber, for the greater part, and including the San Pedro, Tuerto, San Yedro and Sandia mountains, all known to contain mineral. It is 20 miles from the railroad station at Bernalillo to the village of San Pedro, which has grown up centrally, in relation to the copper and gold veins, and the placers. The copper and gold mines are about a mile from the village, at an elevation of about 8,000 feet, and on the west side of Tuerto mountain. The veins are about 30 feet wide, encased in well-defined walls, cropping out laterally for a distance of half a mile, and pitching into the mountain with a dip of 15 degrees. Ore of one strata is composed of carbonates, silicates, and

THE ENGINEER.

A Projected Underground Railway.

The pressure of travel and traffic has become so great in New York city, that the surface scarcely offers sufficient accommodations for its present and growing needs. To meet this want in the least objectionable way it is proposed to construct an underground railway. The *Iron Age* contains a detailed account of the scheme, of which we present a summary. The certificate of incorporation of "The New York Underground Railroad Co.," has been filed in the county clerk's office; the plans for the road are completed; and it is promised that the contracts will be awarded shortly, and that the actual work of excavation will begin this fall. The board of directors is composed of well-known citizens. It is stated that Gen. G. B. McClellan, who is one of the directors, will be the president of the company. It is also said that arrangements have been made in Europe for placing the bonds of the company on favorable terms. It is the expectation of the company that the road will be completed by January 1, 1883, and will be in operation when the World's fair is opened.

The plans for the construction of the road have been executed by Walter J. Morris, C. E. According to these plans, the road will extend from South ferry along the eastern side of the Battery to Broadway and Bowling Green, thence up Broadway under Union square, to Madison square. The main line will continue from this point under Madison square and through Madison avenue to the Central park, beyond which the plans of the company do not at present look. Stations will be placed at convenient distances along the route. The road will be built in this way: Two single-track tunnels, each 15 ft. high and 12 ft. 6 inches wide, will run side by side, and separated by a brick wall. They will lie directly under the middle of Broadway, just below the water pipes, and reaching nearly to the curb on each side. The tunnel will be partly arched and partly supported by beams. The street will first be covered with heavy planks and timbers—in fact converted into a plank road—over which the usual traffic may continue uninterruptedly during the work of excavation. The tunneling will be done from a side street. A working shaft will be sunk just off the main avenue, through which the work will be pushed for a few blocks at a time, until another similar working shaft may be necessary further along. The planking on the surface will be laid for 1,500 ft. at a time, and removed as the tunnel is completed, while underground beams and supports will be placed every 8 ft. ahead until the walls of the tunnels are bricked up. The planking will be laid by night, and thus it is hoped that it may never be found necessary to close the thoroughfares under which the road passes. The tunnels will, as a rule, follow closely the surface grade of the streets, and the tracks will be at an average of 25 ft. underground. On Murray Hill, at Thirty-eighth street, however, the pavement will be 62 ft. above the tracks in the tunnels.

One of the chief advantages claimed for the tunnel will be its dryness. The walls will be built of bricks and cement, with a hard white finish, and covered on all sides with asphalt. It is expected that this will render the tunnel impervious to water and the system of ventilation is relied upon to prevent any dampness. As this will give a uniform temperature in the tunnel, no allowance will be made for the expansion and contraction of the rails, which is necessary in open-air railroads; and the rails will be laid on a hard bed of ballast, covered to prevent dust; with the ends nearly touching in one continuous rail. This method will, it is believed, prevent the usual disagreeable "joggle," and will enable the cars to roll smoothly. Great locomotives of 60 tons, similar to those employed in the London underground railway, will be used; and they will burn coke and consume their own smoke. The exhaust steam will be condensed, and nothing will escape to impair the atmosphere in the tunnel but a little gas. A part of the care will be after the style of the Pullman parlor cars, and there will be a modification of the English railway carriage, with the entrance at the side. It is proposed to light both cars and tunnel by electricity; an electric machine will be placed on each engine to run the headlight and the candles in the cars.

The problem of thorough ventilation has been considered carefully, and the engineers believe it has been solved. At the principal stations air-shafts will rise up 75 ft., and other openings will be made at frequent intervals. Through these air will be introduced by artificial means. A novel feature of the system is making the locomotive a sort of piston head or plunger by means of a broad flange about the cab, reaching nearly to the sides of the tunnel. Each train will, it is expected, force the air ahead as it runs and cause a suction and consequent draft of air in its wake. By having two tunnels, the trains in each running always in one direction, a current of air is thus established. The vitiated air will be carried ahead to the first opening and expelled, while fresh air is drawn in by the passage of the train. In London, where two trains pass in opposite directions in the same tunnel, a whirlwind is caused and the gases and smoke, if any, eddy round, and remain in the tunnel. By the system of two tunnels it is thought that

MINERS and prospectors are quietly leaving Leadville to prospect at Battle Mountain.

this defect can be remedied with but an inconsiderable addition in the power expended.

The underground stations will, as a rule, be under street corners. At the principal points, such as the Battery, City Hall, Union square, etc., splendid ornamental stations will be built on the surface. The plan of the engineer requires first safety and comfort and then ornamentation. The stations underground will be provided with comfortable sitting rooms, and will be thoroughly lighted by electricity. The platforms will be 400 ft. long and 14 ft. wide. Trains of from 8 to 10 cars can be run at a speed, it is estimated, of 25 miles an hour, including stops, and each train will seat from 800 to 1,000 passengers. Trains can be run every three minutes. The fare is to be uniformly five cents. No estimate of the cost of this stupendous project is published, but it will probably be millions for every mile.

Outbursts of Heat in the Sun.

Lately many scientific journals have contained accounts of the observation of new and unexpected variable stars. The more carefully we study the stars the more evident it becomes to us, that a large proportion of them undergo and exhibit changes of light with a certain degree of regularity. Very few stars change their brilliancy so quickly as Algol, the "winking demon," in Medusa's head, but there are many that wax and wane in a remarkable manner.

This subject becomes especially interesting, remarks a writer in the *New York Sun*, when we consider the fact that reasons have been shown why our own sun may be regarded as a variable star. Prof. Proctor in his essay on the "End of Many Worlds," suggests that periodical outbursts of heat in the sun may account for the curious traditions running alike through the Indian, Egyptian, Chinese and Greek mythologies, that the earth at certain epochs undergoes destruction and renovation by fire. On such a supposition the story of Phaeton becomes the tradition of an actual event in the earth's history. According to the myth, Phaeton persuaded his father Apollo to let him drive the car of the sun for a day, lost the road, and, approaching too near the earth, set Olympus on fire, consumed cities and whole nations with flame, and turned the northern end of Africa into a waterless desert.

The cause of any sudden access of heat in the sun, or in a star, is believed to be the downfall upon its surface of a vast quantity of meteoric matter whirling in the track of some comet. We have records of a sudden brightening of the sun in modern times. A remarkable phenomenon of this kind occurred on September 1, 1859, and although it was of very brief duration, it produced startling effects in various parts of the world.

If there is a mass of meteors rushing in an orbit that the sun crosses at certain epochs, and which then causes his fires to burst out with the effects described in the ancient traditions, they have thus far escaped the ken of the astronomers. Observation has shown, however, that if such meteors exist they are to be looked for in the wake of a comet, and we can depend upon the astronomers to give due notice of the comet's appearance.

RAPID FOREST DESTRUCTION.—An intelligent correspondent of the *Cincinnati Gazette*, after an investigation in the pine regions of Michigan, reports the judgment that the mills in the Alpena district have only 15 years' supply left, and adds: These figures agree very closely with those given me a few weeks ago by the president of the largest logging company on the Mississippi river, operating in the Wisconsin pineries, a region that has been worked much less extensively than the Michigan pineries. They would last, he said, 30 or 40 years. The Minnesota pineries are not so large as either of the others, and will probably not survive them. In from 25 to 40 years the last tree will be cut, and the entire country from Maine to the Rocky mountains must learn to live with meager quantities of pine lumber brought at great expense from distant countries. The pineries cannot be replaced. A full grown tree represents hundreds and hundreds of years of growth. I saw small pines, no larger round than a man's arm, bearing the scars made by the axes of the United States engineers 35 years ago. What ages, then, must be required to produce a tree three or four ft. in diameter? When these forests reach the condition of the pineries of Maine and New York, and become extinct, no new ones will take their places. The American of the near future must learn to hew and build without pine, and marvel at the thoughtless recklessness of his ancestors.

OBELISKS AS LIGHTNING CONDUCTORS.—Mr. F. Le Page Roup, a student of the Coptic language, writes as follows to the *Academy*: "A good deal was written some time ago on the subject of obelisks. I am not aware that attention has ever yet been called to an important piece of evidence as to the use of this kind of monument. This evidence is found in an inscription from the temple at Edfu, published by Brugsch Bey in the *Zeitschrift für Ägyptische Sprache*, September, 1875. In the 34th line of this text 'two large obelisks' are expressly said to have been constructed, *her tekles shena enen en Nu*, 'for the purpose of cleaving asunder the storm-cloud of heaven.' Brugsch had already, in the *Zeitschrift* of 1871, p. 143, quoted a similar text in reference to the great flagstaffs of the pylones."

USEFUL INFORMATION.

HOW RAILWAY TIME IS KEPT.—There are in use between this city and New York 13 electric clocks, two of the number being placed in the waiting-rooms and one in the dispatcher's office at the Grand Central depot, New York. The time on the clock in the depot at East Albany corresponds exactly with the time in New York. Each one of the clocks is connected with the General Superintendent's office in New York, in which the railroad time is kept on what is called the "big clock." Conductors, train men and others are compelled to keep their watches in strict conformity with the Superintendent's clock. It is set by standard time, and connected with the time service department of the gold and stock telegraph. The time is distributed over the line each week day as follows: At 10 o'clock 58 minutes and 3 seconds A. M. the word "time" is sent by the main office to the telegraph stations between New York and Albany. This word is repeated for 28 seconds, during which time operators must see that their instruments are adjusted. At 10 o'clock and 50 seconds, seconds commences beating, and continue for 50 seconds. The word "switch" is then sent over the wire, and operators having electric clocks connect them immediately with the circuit known as number 9 wire. Ten seconds are allowed in which to make the connection. At 11 A. M., with one touch of the New York key, the hands on the different clocks are set to 11 o'clock. If they are fast or slow, they change all at once to the hour named.—*Albany Argus*.

SALICYLIC ACID AS A PRESERVATIVE.—A correspondent of the *Journal of Microscopy* says salicylic acid has been strongly recommended in this journal as a preservative, and I have had very good success with it in mounting vegetable preparations of all kinds. One difficulty, however, is that it dissolves very sparingly in water, and alcohol produces changes which are frequently undesirable. It is well known that salicylic acid dissolves freely in a solution of borax, and it is also familiar to most persons that borax itself is quite efficient as a preservative. It, therefore, occurred to me to combine these two, and I have found that two parts of salicylic acid and one part of borax dissolved completely in half an ounce of glycerine, and that this solution when mixed with three parts of water, forms a most excellent preservative fluid for coarse organisms. More delicate preparations should be mounted in the above solution diluted with five parts of water. Preparations mounted with this solution are very durable.

HORSE LEATHER.—By a recent Cabinet order, horse leather has been adopted as the material of which the boots issued to sailors of the German navy are in future to be made. Experiments with horse-leather boots have, it appears, been carried on for the past 18 months, and with such satisfactory results that the use of calf skin is to be altogether abandoned in making naval boots and shoes. The leather used is to be made of the skin of the quarters of the horse, the flesh being carefully scraped off, so as to render the leather soft and pliable, while still remaining, to a large extent, waterproof.

PAPER DISH MATS, which can be washed without the slightest injury, and which very nearly resemble the wicker dish mats commonly used on the dining-table, are among the most recent novelties. The mats are stamped out of cardboard, in both round and oval form and in any desired size. The wicker-work pattern is lithographed, after which the work is finished up by the application of a very hard kind of varnish. The paper mats, it is claimed, will last as long as wicker ones, are much cheaper, and possess the additional advantage of a smooth surface.

SOLDERING LIQUIDS.—The *American Manufacturer* of July 23, 1880, gives the following recipe for soldering liquid: "Dissolve scrap zinc in excess in hydrochloric acid by means of heat, neutralize the free acid with water of ammonia, and dilute with an equal bulk of water." In practice the following has been found as good as the above and easier to prepare: Dissolve chloride of zinc in about twice its bulk of water for iron and steel articles. For copper, brass, etc., it may be diluted to four or five times its volume. The chloride may be had of any wholesale druggist for about ten cents per ounce.

PRESERVING LEATHER.—To preserve leather hose, helting, etc., in good condition, use crude castor-oil, warmed, if possible, and freely applied. It increases the pliability of the leather and the cling of the belts, and does not become rancid. Rats avoid it. In hose it should be pumped in from the interior under considerable pressure, thus thoroughly filling the pores.

MAKE YOUR OWN BAROMETER.—A sheet of paper, dipped in chloride of cobalt, when the weather is to be dry and pleasant will become blue, when wet weather approaches it will become pink. The barometer flowers of France are thus manufactured.

AN ABSURDITY.—To purchase wood by measure. Its heat-producing qualities are in proportion to its weight, if seasoned. When in Paris, our wood was furnished by the pound.

GLUCOSE.—The manufacture of glucose in this country has grown to enormous proportions, there being at present no less than \$30,000,000 invested in it. The material here is made entirely from corn, and so successful has it been, that quite a *fièvre* exists in connection with it throughout the West, where a number of new factories are being set up. This industry originated in the year 1863, with Messrs. Gessling & Bradley, who at that time improvised an experimental factory in Buffalo, to determine if grape sugar and syrup could not be made from corn. The product had been made for years in Europe from potatoes, and imported into this country at prices ranging from 8 to 12 cents per pound; but up to that time sugar from corn was not known as a commercial article. The experiment was successful, and from this beginning has gradually developed what is now an immense industry. At the present time, instead of importing from Europe an inferior article of grape sugar made from potatoes, at a cost of from 8 to 12 cents, as above noted, large quantities of corn sugar are exported at about three cents. A bushel of corn produces 30 pounds of glucose.

TO TEST MILK FOR WATER.—A German chemist furnishes a very simple procedure for testing the amount of water in milk, which can be applied by any one. All that is required is a small quantity of plaster of Paris, say one ounce. This is mixed with the milk to a stiff paste, and then allowed to stand. With milk of 1.030 specific gravity, and a temperature of 60° F., it will harden in 10 hours; if 25% of water is present, in two hours; if 50% in one and one-half hours, and with 75% in 30 minutes. Skimmed milk which has been standing for 24 hours, and is of 1.033 specific gravity, sets in four hours; with 50% of water, in one hour, and with 75% in 30 minutes. Heat should not be applied, as then the use of the thermometer would be required. This test is certainly very simple, and not costly.

A SUBSTITUTE FOR EMERY.—Garnet is now being extensively used as a substitute for emery. It has been introduced both for wheels and for paper—the latter being known as "ruby paper."

GOOD HEALTH.

How We Starve by Overeating.

EDITORS PRESS:—Dr. Tanner's fast has given us new light on the important question, how long a robust man may starve himself without permanent injury, and, perhaps, with positive benefit. But the very common case of starving oneself by overeating is to most people (though few know or think it) of much greater personal interest. It is because the statement that we can, and too often do, starve ourselves by overeating seems so paradoxical, that I hope every reader of the PRESS will do himself and friends the justice of seeing if it is true. How often do kind friends persuade the tired mother to eat a little more; or the worried man of business to take an extra lunch or supper, when already the body is at its utmost strain and can no more digest an extra meal than it can undertake extra labor. No man in these busy days can afford to neglect the stern fact that digestion is labor, and in weak persons often just about all the labor they are capable of. This fact is daily recognized in hospitals, especially by the surgeon, who, dealing most with the accident cases, has comparatively healthy stomachs to deal with. Yet here, when all the strength has to be husbanded to meet the strain of a surgical operation, a surgeon dislikes to operate before he has put his patient through a course of simple diet, with rest. Generally too he gives him such medicines as will excite the bowels, kidneys, etc., to carry off those waste matters from his system which too often are simply due to gross feeding.

It would take too long, and probably also convey less of the real truth, were I to go into detail and show the nature and magnitude of the digestive processes. A glimpse of it may be gathered from the fact that our best authorities agree that the internal muscular labor of the body consumes about four-fifths of our daily strength and food; that is, that the churning, straining and pumping of the food and digestive fluids uses up most of our food to make the remaining fifth available for use in our daily labor. This is a big thing I hear some one exclaim. Yes, and the following may, perhaps, seem bigger: Thirty lbs., or nearly twice the weight of the whole blood in our bodies, is poured out daily from the blood vessels (and of course absorbed again when its work is done) into the alimentary canal for digesting purposes. Our two best authorities—Playfair and Letheby—differ but very slightly in their estimates. The average of both states that daily the blood secretes $\frac{3}{4}$ lbs. of saliva, $\frac{1}{4}$ lb. of gastric juice, $\frac{8}{9}$ of pancreatic fluid, $\frac{3}{4}$ of bile and $\frac{1}{2}$ lb. (I believe much more) of intestinal fluid. By measure this comes to 21½ English pints, or more than three American gallons; and all this has to pass through miles of little tubes too small for the naked eye to see. Evidently the 17 lbs. of blood with which physiology credits the average man has to be active all the day long. The blood much resembles a restaurant waiter, who is constantly passing from the kitchen (the stomach, etc.) to the dining hall (visceral veins—lymphatics) with viand of all kinds, and as

constantly returning again with the dishes, the spoons and whatever the guests refuse.

These various digestive fluids are beside of different chemical composition. Each one, too, contains a special organized ferment, powerful to the digestion of some special part of our food. Now these ferments are in a sense like the seed of a plant, and their production must exhaust the organ producing them much as the seeding of a flower exhausts the plant producing it. No wonder then that indigestion is the rule and not the exception in this bustling busy age.

If a man must, then, overwork, let him beware of overeating. Many ignorantly overeat, deluded by the temporary pause that each meal gives to that feeling of continuous exhaustion, which is quite as often caused by excess of food as by excess of work. This temporary strength is probably due to the stimulation of that great epigastric nervous flexus [which is close to the stomach. It has charge of the digestive process, and by food it is excited, and receives an extra supply of blood, just as the eye is excited to action by light, or the ear by sound. This great flexus is the focus of sensation for the abdomen, and its exhaustion we call hunger; but I guess Americans oftener exhaust it by too big than by too little meals, and either cause, it is evident, may give a feeling of hunger. Most of us could easily pick out from among our acquaintances many more examples of weak people who eat much than of weak ones who eat little. The big eaters probably are weak because they habitually eat up to their fullest vital capacity, and are, in fact, like so many hogs—living to eat, instead of eating to live.

But overeating does not merely use up all the working strength in digestion. Unless limited very strictly to the point of complete digestion, much of the food may pass through only the first stages of digestion. It may be acidified in the stomach, but fail to get neutralized in the bowel, where fermentation of an unnatural kind will cause flatulence, and give rise to impure fluids. These absorbed into the blood give feebleness of constitution and liability to disease, and at the same time overload and overwork the liver, kidneys, lungs, skin, and all purifying organs. This habit is the commonest cause of many of our complaints.

To the man or woman who overeats and will not work I have nothing to say. He or she is a hog. But to the wearied mother who wants strength to get through her work I would say: Aim first at eating those foods which need least digestion—roast or broiled mutton, toasted bread (buttered when cold), boiled rice and milk, oatmeal mush, milk diet of all kinds. And here let me remark that milk will, as a rule, agree with any one, if well boiled, and then diluted one-half with weak tea or coffee, or any other fluid, to taste. Many people find that milk does not agree with them, but, boiled and diluted, it seems quite to lose its bilious nature. Eggs, too, are good; also simple soups, and ripe fruit, raw, or cooked with a little sugar. Apples, well washed and baked in the oven, no stomach will feel—it is the sugar of cooked fruit that so often disagrees. Do not attempt too many meals, or have them too near each other. New food introduced into a stomach just finished with and about to pass the last meal into the bowel, may disturb the process, and spoil both the new and the old. Yet something may be taken between meals, if it be nearly all fluid—say a little beef tea, made with cold water slowly heated up just to a boiling point, or a little gruel, made with rice, oatmeal, graham flour, etc. Stir up a tablespoonful of one of these with as much cold water as will thin them to the consistency of cream. Then pour on a pint of boiling water, stir well, and salt it to taste. This has the advantage of being quickly made. A baked apple, a pear, an egg beaten up with a little sugar and water, or any of these simple things, will not only give strength, with almost no labor in digestion, but, taken an hour before food, often give an appetite, and ensure the better digestion of the following meal.

SANTARIAN, M. D.

THE DISEASES OF UNDERWORK.—A medical exchange says: We have heard a great deal about the diseases of overwork, and it would be interesting to see if something cannot be said now regarding the "diseases of underwork." That man is naturally a lazy animal is a proposition often made and never refuted. We have a great many lazy people even in this country. It is to be hoped that some enterprising pathologist may make a special study of these. He may find a new disease. There are certainly cases of adiposithenia and gastrosthenia. Who will be the first man to write a book on the subject?

LUNG AND LIVER COMPLAINTS are certainly benefited, often cured, by a free consumption of onions, either cooked or raw. Colds yield to them like magic. If this esculent be taken at night all offence will be wanting by morning, and the good effects will amply compensate for the trifling annoyance. Taken regularly, they greatly promote the health of the lungs and digestive organs. An extract made by boiling down the juice of onions to a syrup, and taken as a medicine, answers the purpose very well, but fried, roasted or boiled onions are better.

A WRITER in the *London Lancet* remarks that at the Middlesex hospital, female patients who have suffered many years from sick headache, evidently of a hereditary character, have been greatly benefited, if not cured, by the administration of ten minim doses of tincture of Indian hemp, three times a day, between the attacks.

The Week.

City and country are now in the full enjoyment of sweet autumn days. This is perhaps on this coast the most delightful season of the year. The weather is charmingly variable, clouds and mist and a chilly atmosphere are followed by brilliant sunshine and a larger measure of ozone, which imparts new vigor and buoyancy to the spirits, and impels man and beast to move with increased "snap." Vintage is now in the full flush of realization, and the poetry of the vineyard and its gold and purple clusters are giving way to the practical phase of raisins and wine. In the mining regions many of the companies have finished their season's work, which has been generally prosperous, and are busy in their preparations for the coming season of rain and snow. In other counties again, where the conditions are more favorable, mining progresses without interruption. The year has advanced sufficiently to indicate that it has been unusually prosperous to the miners of this State.

In this city during the week a noteworthy incident has occurred, which is full of interest to our residents. Mr. R. H. McDonald, a well known and wealthy citizen, has submitted a proposition for the establishment of a "Christian University" in this city. He proposes to give the munificent sum of \$100,000 on the

condition that the university shall be established in conformity to certain articles which he has drawn. This is the first instance in the history of the State where any of her wealthy citizens has made available during his lifetime so large a gift for the purposes of education.

The Author's Carnival, which opened brilliantly on Monday evening at the Mechanics' Institute pavilion, is in the full tide of success. The first night was graced by the presence of the Presidential party, and the splendid scene has never been excelled in San Francisco. As the affair is designed to aid our home charities, it is pleasant to mention that its success may be regarded as fully assured.

The State fair at Sacramento city is in full progress, and the display in every department is represented as complete. So great has been the demand of exhibitors that there is complaint of a want of space in the pavilion. The attendance is large, and was increased doubtless by the visit of the President.

A Quick Collapse.

About four weeks ago the stock of the San Pedro and Canyon Del Agua mining company of New Mexico took a sudden jump in the New York market from about \$1.25 per share to \$7. The reason assigned was the announcement that Gen. Grant had accepted the Presidency of the company. Since then many people who lost heavily by the rapid decline of the stock have complained that the Grant story was empty and solely a "hoom" to raise the price, and that after the operators had secured their pile they allowed the thing to collapse by announcing that the ex-President had changed his mind and declined the proffered honor.

This is the news that comes to us over the wires from New York, and serves as an illustration of the absurd ideas many people have of mining operations. If they invested in that stock simply because Gen. Grant was to be President, they invested more on the individual than the mine, and more on a stock-gambling deal than a legitimate piece of business. How Gen. Grant or any other illustrious man could benefit it more as a mine is more than we can see. His name would serve to float the stock, it is true; and it was on this basis that people bought the stock, hoping it would rise and they could sell to others. Having been taken in themselves in the same sort of way they wanted to take in others, we have no sympathy for them whatever.

Gen. Grant acted with his usual good sense in declining the Presidency of a mining company. He never pretended to have any knowledge of mining matters at all, and was of course only wanted to give tone to some company that needed great assistance in being brought before the public. A legitimate enterprise would be more likely to go on its own merits.

At any rate the people who lost money on the venture are not to be pitied in the least degree, as they were "done" as they hoped and expected to "do" others.

Mining Company Presidents.

It is worthy of note that in all the new mining companies formed in the Eastern States great care is taken in the selection of president, and every effort possible is made to get men of prominence to take the position. In this we see evidences of tendencies toward stock dealing rather than mining, as no such trouble seems to be taken in selecting a superintendent. We have got over this ourselves some years ago, and look upon the president of a mining company in the light of a superfluous individual, rather to be tolerated than brought prominently forward.

In fact, he is, as a general thing, merely a figure-head. He draws a salary, usually a big one, and does not do anything for it. He is supposed to be a sort of financial manager and presides at directors' meetings. As far as contributing anything at all to the resources of a company he is utterly useless.

It is only large companies, with stock for sale, that need a president at all. Some of our big mining magnates have one president who does duty for dozens of companies in which they are interested. He doesn't do anything and is not expected to do anything, and wouldn't know how to do anything if he were asked to. Lots of these presidents never visited their mines and hardly know where they are.

The superintendent is the officer who is the important one as far as the actual mining goes. It is he who plans, arranges and carries out. The president seldom knows anything of mining, practically. In fact, in nine cases out of ten a president is not needed, except to comply with a State law or for some such reason. They may and do help to float companies on the stock markets, but as far as any assistance to actual work is concerned, might as well be left out of the list of officers.

MESSRS. WHITTIER, FULLER & Co. were especially fortunate at the recent Mechanics' fair. They received a gold medal for best display of paints; a silver one for prepared paints for general use; and another gold one for lead and its manufacture. If we recollect aright they are the only exhibitors who received two gold medals.

Ice Water for Miners.

When the cage fell in the Imperial shaft on the Comstock the other day, only one of the 10 men who fell with it was saved, and he was cut and bruised from head to foot. He has a cut on the back of his head that reaches down to the skull, and is nearly four inches in length; also a cut above his right hip that reaches through into the cavity of the abdomen. He was able to converse, though appearing somewhat drowsy in his actions. He said he could remember nothing about the accident; that it seemed to him as if he had been asleep. He could not remember getting aboard the cage to start up.

A suggestive fact in connection with the accident as related by the *Enterprise* is, that when brought up out of the mine and still wandering in his mind he spat out the brandy that was put in his mouth, but when tried with ice water he eagerly grasped for it and drank it. Dr. Harris seeing this eagerness allowed his patient to have all the ice water he would drink, and found that the effect was excellent. Of course accidents frequently occur around the mines, and heretofore it has been the practice to pour brandy into wounded men. The doctor is now of the opinion that in many cases ice water would do them more good. All miners are used to drinking great quantities of ice water in the heated levels. When an accident occurs to any of them down in the hot regions of a mine the chances are that, although unconscious, they are almost burning up with thirst by the time they reach the surface, and all they ordinarily get is brandy or whisky, which must heat instead of cooling them. If given brandy or whisky men under these circumstances should doubtless also be offered water. After this experience this will no doubt be done hereafter.

Underground Iron Structure.

For wide levels, air-ways and principally transport galleries, wrought iron structures are introduced in European mines, in the shape of arches or ellipses made of double T iron. Such iron fastenings were exhibited at the Dusseldorf exhibition by the Saarbrücken mines, the Hibernia colliery, the Phoenix company and the Gutehoffnungshütte iron and steel company of Oberhausen. Another species of underground iron structure are the water-tight trap doors in water-tight dams of masonry, which in the principal levels are walled across at certain places, in order to secure the vital parts of a mine against the sudden inroad of water from the water-bearing strata above the old workings, which may possibly settle down in such a way as to open a way for the water. These dams are provided with one or two strong iron trap doors which allow the ordinary passage, but in case of need can be secured by water-tight packings and strong fastenings. All provident European mines have secured themselves in such a way against a sudden drowning out; for instance, the collieries Westende, Tremonia, Riugeltanhe, Maria Anna, Neu Coln, Holland, Hanover, Engelsburg, Constantin and many others. Such iron trap doors weigh nearly two tons each, and are made of thick boiler plates. In case that part of the mine behind a dam should have run full of water, there are pipes with valves provided which pass through the dam and allow of a gradual tapping off.

Social Science Club.

Realizing that the heterogeneous population of this State, and especially of this city, is called upon to act in many emergencies incident to new countries without the benefit of the knowledge and experience of older communities, and that this generation is founding a society on these isolated shores, which must suffer for our mistakes, a few gentlemen have conceived the idea of establishing in San Francisco a Social Science Club, with the design of eliciting the best work of some 50, more or less, of our best minds in the monthly discussion of those topics of social science most interesting in California, and of influencing public opinion in the direction of economic truth.

A preliminary meeting is to be held in the rooms of the Board of Underwriters, 418 California street, on Monday evening next. The call for the meeting is signed by such gentlemen as George Davidson, Horace Davis, Eugene Casserly, John H. Boalt, C. T. Hopkins, Horatio Stehbins, John N. Pomeroy, Alex. Del Mar and Ralph C. Harrison.

IRA G. TODD, an ingenious machinist at the Florence sewing-machine shops, has invented a new mechanical motion which will be of use for sewing-machine work, silk and other light machinery. The motion is a positive one and is to drive the shafts at right angles with each other, any distance apart, without using bevel gears. The motion consists of a peculiar double eccentric and ordinary pitman connecting on the end of the crank arm of the lower shaft. This motion has long been sought for in mechanics, so that the noise of the bevel gears could be dispensed with.

The Lick Observatory on Mount Hamilton.

At the last meeting of the California Academy of Sciences the report of Prof. S. W. Burnham, of Chicago, to the Lick Trustees, was received. The report is on the observations made at Mount Hamilton with reference to the erection of the Lick observatory. The trustees state that the preliminary work on Mount Hamilton has already been commenced, and will be prosecuted as rapidly as possible under the circumstances. The smaller equatorial telescope, of twelve inches aperture, has been ordered from Alvan Clark & Sons, of Cambridge, Mass., and will be placed in position early in 1881, and the great equatorial telescope, meridian circle, and other instruments, will be contracted for at an early day. It is not expected there will be any further delay in putting the Lick observatory in complete working order, other than that incident to the importance and magnitude of the undertaking.

Prof. S. W. Burnham, who has made observations from Mount Hamilton, speaks of its remarkable fitness for the site of an observatory. There is a wonderful freedom from clouds and fog. The elevation is 4,250 ft. above the sea, and the north peak is 140 ft. higher. The view from these peaks is unobstructed in every direction, there being no higher ground within a radius of 100 miles. The scope of the horizon from Mount Hamilton takes in more ground, according to Prof. Whitney's judgment, than almost any similar peak in the United States, there being no obstructions to the view from any quarter. The Pacific ocean can be seen on the west, Lassen hutte on the north, and the Sierra on the east. Prof. Burnham's preliminary observations at Mount Hamilton were taken by a six-inch refractor, and a temporary dome was erected 12 ft. in diameter, and made to move on 12 iron balls. Out of 60 nights, 42 were simply perfect, first-class nights, and 7 were good, while 11 only were cloudy. Most of the nights were perfectly calm and still. One of the most important conditions is the remarkable dryness of the atmosphere, which is particularly favorable to telescopic observation. Prof. Burnham reaches the conclusion, from his observations made upon Mount Hamilton, that the site chosen for the Lick observatory offers advantages superior to those found at any point where a permanent observatory has yet been established upon earth. The remarkable steadiness of the air, and the continued succession of nights of almost perfect definition, are conditions not met with elsewhere. The low altitude at which observation can be made is a matter of marked importance, particularly in connection with the southern sky, not ordinarily accessible to observations in the northern hemisphere. The ease with which difficult objects can be seen, almost down to the horizon, is very important. He observed close pairs of double stars down to forty-three degrees, or more, of south declination. The permanent steadiness of the air during the whole night will greatly increase the amount of telescopic work over what could ordinarily be done on good nights in most places.

Prof. Burnham prints a catalogue of 42 new double stars discovered at Mount Hamilton, thus practically demonstrating that work has already begun in earnest; and he requests that the various publications of observatories and of astronomical and scientific societies may be sent in exchange for the permanent library of the now located Lick observatory, on Mount Hamilton, California.

TROUBLE WITH OHIO COAL MINERS.—There has been serious difficulty at the Corning coal mine, Ohio, between white and colored miners. On the 15th inst. Gov. Foster and Adjutant-General Gibson received telegrams from Corning, Perry Co., stating that serious trouble might occur by reason of an attempt by a mob of over 1,000 miners from Strateville and Shawnee to drive colored miners away from that locality. The operators armed their colored miners, and proposed to protect their property, if possible. On the 19th the sheriff of Perry county ordered a company of militia to the scene, and later called on Gov. Foster for additional troops. In response to this call, Gov. Foster ordered parts of three companies of the Fourteenth Regiment, to proceed at once to Corning. In response to a riot alarm sounded by the Fire Department at 4 o'clock, these troops assembled at their armory, and left for Corning at 12 o'clock by special train. At 7:30 P. M., a telegram was received by the Adjutant-General stating that during the exchange of shots this evening between the militia and miners, three miners were known to have been wounded, but none of the militia were injured. A special to the *State Journal* says: This evening the miners charged on No. 3 mine on three sides. The troops opened fire on them, when an inglorious retreat was made. There are about ten wounded, nine of them seriously. While in retreat, shouting and shooting were going on promiscuously. At midnight a telegram was received by Assistant Adjutant-General Smith, stating that all was quiet and that no further trouble was anticipated.

On Thursday evening, a young man named Joseph McCulloch, aged 17, while working in a mine at Georgetown, El Dorado county, with his father, was caved upon, and before he could be rescued life was extinct.

Awards to Pacific Coast Inventors.

We are pleased to note among the exhibitors at the Mechanics' Institute fair, to whom premiums were awarded, a number of inventors for whose inventions the MINING AND SCIENTIFIC PRESS Patent Agency has procured patents. In looking over the list we observe that most of these patentees carried away, as they deserved, the medals in their classes.

The Rice straw-burning engine received a silver medal. This device is in extensive use on this coast and has been introduced in the East, and has proved itself a very useful invention.

Mr. Phillip Hinkle, a deservedly successful inventor, has received a silver medal for his hydraulic elevator.

Pacific Saw Manufacturing Company received a gold medal; Mr. N. W. Spaulding receiving a silver medal for his inserted saw tooth. This tooth is one of our best-known and most widely-used California inventions.

Mr. B. E. Henriksen, whose safety clutch for elevators, although a recently-patented invention, has been very rapidly introduced, took a silver medal; as also did Mr. Culver's patent pneumatic stop for elevators.

D. B. James' single-track railway, soon to be brought to practical test over a long road, obtained a silver medal.

Frellicher & Mahler took a silver medal for their new hand and foot-power washing machine.

Batchelor & Van Golder, of Sacramento, were awarded a bronze medal for their spring-tooth harrow.

Mr. Byron Jackson, an inventor who has turned his attention more particularly to agricultural implements, received a diploma for his light-weight horse fork, now extensively used in California harvest fields.

Mr. A. S. Hallidie, the well-known wire goods manufacturer, is among our foremost inventors, his attention having turned more especially to cable railroads and cable transportation. He received a gold medal for his wire rope goods, and a silver medal for his wire rope.

Mr. W. A. Wiester received a silver medal for his coal-nail stoves.

Messrs. Morris & Son, inventors of pneumatic signal devices, took a silver medal for their bronze door locks and hinges, and another silver medal for their pneumatic signal and annunciator.

Gladding & McBean carried off a silver medal for their sawer and drain pipe.

J. Browell, who has made a specialty of cement chimneys, received a silver medal for a chimney top.

Mr. E. J. Verrue, who has invented a hydraulic waste-pipe cleaner by which a drain pipe may be cleaned in the most effective manner, received a diploma.

Wilson's gas valve sewer trap took a silver medal.

Levake & Grubb received a bronze medal for their water closet.

Mr. Geo. H. Fuller, an inventor of important inventions in the construction of school furniture, received a silver medal.

P. Kelly, the "priza boot and shoe maker," received two medals; one for the combined boot and shoe, an important invention of great utility, and the other for hand-made shoes.

Wm. Sack, for a measuring device applied to tanks or water closets, received a silver medal.

Frank Laerman obtained a silver medal for the best sofa bed, which is quite a triumph, as the device is a new one, the first sofa beds made after the improved pattern being those exhibited at the fair.

Messrs. Hartshorn & McPhun received a silver medal for window shades and fixtures.

Mr. M. B. Dodge for his etono breaker and ore crusher obtained a silver medal.

E. F. Russell took a silver medal for his amalgamator.

Frank A. Huntington exhibited his new oscillating ore stamp, and was awarded a silver medal.

Foundry Notes.

The Pacific Iron Works have recently shipped a 20-stamp mill for the Boston & Arizona mining company, at Contention City, Arizona. This plant comprises the most expensive and complete mill yet constructed for the Territory.

Among other things recently shipped, or being constructed at these works, are a 60-ton Howell furnace and drier, and a set of hoisting works for the Silver Bow mining company, at Butte City, Montana; also a 65-ton Howell furnace and mill machinery for the Marsac mining company, at Park City, Utah; a 30-ton galena-ore furnace outfit for the San Xavier company, in Arizona; one for a New York company operating at Gila Bend, in Arizona; a 35-ton copper furnace equipment for the Martin & Ballard company, at Bisbee City, near Tucson, Arizona.

This firm makes a specialty of water-jacketed smelting furnaces, and have constructed all of this class of work now in use on the coast. They are just completing the machinery for the new propeller of the Eel River Navigation Company, which will be one of the most complete pieces of work of the kind ever made here.

Henriksen's Elevator Clutch.

We illustrate beneath the improved safety clutch for elevators invented by B. E. Henriksen, of this city, and recently patented by him through the MINING AND SCIENTIFIC PRESS Patent Agency.

The safety clutch is a device intended to catch and sustain the cage in case the hoisting rope breaks or the hoisting apparatus is deranged. Trip levers are pivoted to the frame of the cage, and have toothed cams at their lower end. They are inclined outward, and have at their upper ends, rollers which bear against irregularly formed cleats or horses on the sides of the guide-posts. At the ordinary rate of speed these rollers move along on the edge of the cleats, these cleats being formed in wave lines. Should the cable part, or any portion of the machinery break, the rollers are brought in violent contact with the cleats, which, having a sharp incline on the top part, will throw the trip levers over, and bring the clutches or cams in violent contact with the guide-posts, so that they engage with them, and act as brakes or safety levers, preventing the cage from falling farther. The eccentrics, or cams, are toothed, and form a powerful brake, which increases in power in proportion to the strain which is brought upon them.

Mr. Henriksen has exhibited the workings of his device by loading the platform with 700 or 800 pounds of sand-bags. He first runs the elevator up and down at an ordinary rate of speed, to show how it works. Then he throws off the brake, so as to show how it operates in case of an accident to the rope or cylinder on which the rope winds.

The cage is instantly checked whenever the rope breaks. This form of clutch is to be preferred to those whose action depends upon springs. An instance is recorded in another column of loss of life from the non-action of the springs of a safety. This device is adapted for cages in mines as well as for elevators.

The operation of the device depends on speed alone. At the ordinary rate of speed the cams are not brought into action. The moment, however, that the speed becomes too great for safety, the trip levers operate, and the cage is stopped. This device is in use on elevators in the following buildings: Johnson building, No. 120 Sutter St.; Thurlow block; S. F. Stock Exchange; No. 545 Market St.; W. Cohn, northwest corner of Battery and Bush Sts.; W. J. Sloan, 545 Market St.; J. Ceri & Co., 517 Market St.; Halleck block; California Furniture Co., 226 Bush St., etc.

Henriksen's Clutch For Elevators.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

BREAKING CART.—De Witt C. Putnam, Pat. aluma, Cal. Patented Sept. 14, 1880. No. 232,207. This invention relates to certain improvements in that class of vehicles known as "breaking carts," in which young colts are broken to harness. Carts of this description are usually provided with very long shafts, and the seat is placed on springs immediately over the axle, or at such a distance back that the driver is not in danger of being kicked by a fractious animal. In this class of vehicles the foot-board is usually secured to the axle while the seat is on springs, and it is therefore uncomfortable to ride upon, since while the body of the occupant may move up and down his feet must remain stationary. The improvements consist in so attaching the foot-board to the vehicle that it shall move in unison with the seat, the same spring which supports the seat serving as a spring for the foot-board.

WIND-WHEEL.—John C. Preston, Arcata, Humboldt county, Cal. Patented Sept. 14, 1880. No. 232,205. This invention consists in forming an open skeleton-wheel revolving in a horizontal plane, and hinging on vertical rods a series of frames carrying the vanes or fans, these frames being adapted to swing edgewise to the wind on one side, but on the other side to be held by sliding movable lugs, so that their surfaces are exposed to the wind and the wheel caused to revolve and furnish power.

THERE are still 100 miners at work at the Cassiar mines, but steamboat navigation has closed on the Stickeen river for the season.

Another Mining Shaft Accident.

A very serious accident occurred last week at the Imperial mine shaft, on the Comstock, by which nine miners were killed. The cable broke, its safeties failed to work and a double-decker cage fell to the bottom of the shaft, only one of the ten men on it being saved. The 11 o'clock shift had gone down the south compartment on a double-decker cage, and the shift relieved got upon the cage at the 1300 station, which is at the bottom of the vertical shaft, to be hoisted to the surface.

The pumpmen, Richard Ryder, had an ax that had been left at the station the day before, and it is supposed that the ax was lying upon the deck of the cage. The Virginia Enterprise thinks it is probable that the ax slipped over the edge of the cage and caught under one of the timbers, and was thrown in such a way as to catch edge down between the cage and guide, thus forming a wedge which prevented the ascent of the cage, and caused the breaking of the cable. At all events, just at this point the cable was snapped at the reel in the hoisting works.

The engineer, B. F. Jones, says the cable snapped instantly, and the engine began running at such a speed that he could not tell whether it was in consequence of a sudden strain or even sea just where it broke. The cage fell like a shot to the bottom of the shaft, followed by 1,200 ft. of cable, but did not jump out of the guides. It fell with such momentum that it broke the chairs and went below the station, the upper deck stopping at the station level, and the cable coiling upon the floor. The shock was tremendous. Eight men were killed instantly by being thrown against the timbers and the cage and by the weight of the cable falling upon them. The bonnet of the cage was crushed and the decks bent out of shape, but the upper deck was not broken through. The men who were killed were horribly crushed some of their heads being mashed to a jelly and their necks broken.

As soon as possible after the accident help descended the next compartment to the scene of the disaster. It was, however, some time before the men could be extricated. When relieved John Roach and Frank Smith were found to be alive, and Roach talked a little quite rationally. In taking him to the surface he weakened rapidly, and lived only to get to the top.

Following are the names of the killed: John Roach—Single man; both legs broken and side crushed in; died of internal injuries.

Patrick Murphy—Single; literally disembowled, thigh

smashed and skull crushed in.

Richard Ryder—Single; head cleft from crown to eyebrows, shoulder torn nearly off, and the blade driven into his body.

Thomas Meagher—Leavee wife and five children near the Homestead; head crushed and brain all gone; badly bruised all over.

Mat. Winnia—Married; three children; top of head all gone; right arm crushed and nearly torn off; badly bruised.

Joseph Hanrahan—Single; face cut and badly bruised; injuries mostly internal.

William Corbett—Single; head smashed in; upper and back portions of body badly broken and bowels out.

N. B. Farnum—Single; legs badly bruised; injuries internal; most of body black and blue with bruises.

Jerry Sullivan—Leavee wife and three children; head badly cut and bruised all over.

Frank Smith, the only man who was saved, was standing on the upper deck, and when the cage began falling, caught hold of the crossbar with both hands and raised himself clear of everything. His presence of mind saved his life. Of course he was thrown violently to the floor when the cage stopped, and was badly bruised from head to foot.

The cause of the cage falling is referred to elsewhere in these columns. It was due to the non-action of the safety clutches.

NORWAY is talking of cutting loose from Sweden and setting up a republic. The Norwegian Parliament insists upon its right to summon the ministers of the Kingdom before it. The ministers having refused, the Storting passed a bill declaring in few words that "the King's ministers ought to sit and speak in the Storting." The bill was promptly vetoed by King Oscar. The Norwegian constitution provides that the king may veto a measure three times, but that if it passes a fourth time it shall have the force of law without his approval. Although the king dissolved the Parliament, the bill has been carried four times, and now his Majesty rests his refusal to allow it to become law on his prerogative.

Iron Linings for Mining Shafts.

Among the late improvements for shaft sinking in vogue in Europe is a shaft-boring apparatus used in connection with iron-lined shafts. Dr. A. Gurlt, of Bonn, describes, in *Iron*, an apparatus of this kind exhibited at the Düsseldorf exposition. The Kind-Chaudron system was successfully employed by director Bruno Schutz in sinking five shafts at the Dahlbusch colliery through the water-bearing marl of the Cretaceous formation, which overlies the coal measures, while by the Lippman system the shaft of Konigsborn colliery, near Unna, was lately completed with full success and under similar circumstances. Shaft-boring machinery and iron tubing for securing the shafts are specialties of the firm of Haniel & Lueg. The borer which had done the work at Konigsborn, and which alone weighs 21 tons, was exhibited *in natura*. It has the diameter of the whole shaft, and by being lifted and dropped alternately under water it disintegrates the bottom of the shaft, while it leaves the sides entirely unharmed, and the water filling the shaft exerts a counter-pressure upon them. The Kind-Chaudron system, which has lately come into use at the Mansfeld silver and copper mines, differs from the former in so far as in the center of the shaft a wide bore hole, but of very much less diameter than that of the shaft, goes in advance, and the ring of rock which remains around it is then bored out, when all disintegrated rock collects in the middle hole, from which it is easily brought to surface by the so-called ladle. Shaft boring has proved to be particularly advantageous whenever the rocks which shall be reached are covered by thick water-bearing strata, as for instance of the Cretaceous formation in the north of France, in a part of Belgium and Westphalia. By the Kind-Chaudron system no less than 18 shafts in France, 11 in Belgium and 5 in Westphalia were sunk in this manner in less time and with less cost as would have been possible in the ordinary manner of sinking.

Bored shafts are necessarily round, and for their security they require an inner lining either with masonry or iron. The method of lining with iron or tubing is generally adopted, and large cast-iron rings are let down in the pit and are most accurately piled one upon the other until they reach the surface. The space necessarily left between the tubing and the rock is then filled with cement or concrete in order to make it water-tight, and after it has hardened the water is pumped out, and the bottom of the shaft becomes for the first time accessible. Such huge cast-iron shaftings for the Seegangottes shaft, near Eiselen, were exhibited by Haniel & Lueg; they were 4 meters diameter, 1.5 meter high and weigh 10 tons each.

For shafts which can be sunk without much water in the ordinary way, a different system of tubing with cast-iron segments came first into use in the north of England, and in 1856 it was introduced by an English miner, Wm. Coulson, to the Hibernia colliery in Westphalia. Coulson was an illiterate, self-made man, but first-rate in sinking and tubing shafts; and when he died, not long ago, he had sunk and tubed no fewer than 23 shafts in England and 5 in Westphalia. Since then the English system has been largely adopted, and cast-iron segments or tubings were exhibited by Haniel & Lueg, and by H. Horlobe, of Ruhrort. They are 1.30 to 1.33 meters long, 0.60 to 0.64 meters high, and provided with flanges all round, and with ribs on their inner side. Another kind of securing round shafts with rings made from shaped wrought iron, has of late found much favor in several continental mining districts. The Phoenix iron and steel company, however, showed the iron pit-lining *in natura*, by producing a system of two rings which have 5 inches diameter; the rings are connected by eight struts, one meter long, and by two large cross beams of double T iron. They are divided in three compartments, when the middle compartment is again divided by two short iron beams in a large section in the middle and a small one at each end. The cross beams not only strengthen the pit-rings, but at the same time they are intended for separating the pumps from the shafts, and for offering facilities to fasten the pumps and guide-rods for the cages truly and securely.

YUNG KWAI, the Chinese boy who was graduated from the Springfield (Mass.) high school last June with the salutatory address, became a Christian, and wrote home about it to his father, who is one of the highest of the Chinese nobles, though not of royal blood. The father wrote a very indignant letter and ordered him to return home, threatening to starve and beat him into renouncing his views. As the boy was determined to be true to his new faith, he looked upon his return to China as going to almost certain death; but he started quietly with other boys for Boston, whence they were to sail for home by way of Europe. Yung Kwai, however, stepped from the train in Springfield, and that is the last that has been seen of him. If he succeeds in keeping hidden for a year, he will then be 21, and can become a citizen of the United States.

It is now alleged that the use of Gen. Grant's name with the Presidency of the San Pedro and Canyon del Agua Mining Co., of New Mexico, was only a stock-jobbing operation of the managers, who profited largely by it.

Outlandish Dress in England.

It is not surprising that a large crowd should have collected, that ladies were shocked and policemen scandalized, by the appearance lately in the Strand near the Vaudeville theater, at midnight, of a young man dressed in a suit of bed-chintz of various colors. A high-crowned hat completed the costume of this fantastic individual, whose eye-brows were painted black, while the lower part of the face was daubed with red, and who carried an umbrella in one hand and a rifle in the other, in addition to a sword and pistol in his waist belt. The young man was arrested, and when charged the following morning at Bow street with "disorderly conduct," his defence was that he had made a bet of five pounds with a friend, seemingly as brainless as himself, that he would walk from the Criterion to the Gaiety theater in any costume which his friend might prescribe without being molested by the police. Mr. Vaughan eternally reprehended the inopportune masquerader, and ordered him to find one surety in £20 for his good behavior for six months.

Sociologically, the offence of this silly youth was a dual one. He had not only caused an obstruction in a public thoroughfare, but he had committed that which, in England, is deemed a very flagitious offense. He had appeared in an unaccustomed garb. On the other hand, he might, with perfect immunity, at high noon as well as at midnight, in Regent street or in the Strand, at an aristocratic garden party or in the presence of royalty itself, appear in a costume somewhat like the following: A wooden cap with an eagle's feather and silver aigrette in the form of a thistle; a boy's jacket ornamented with many buttons; a short petticoat, fantastically chequered in "various colors;" bare legs; plaid worsted hose with a knife and fork at one garter and a spoon at the other; and hanging before him at his waist a goatskin pouch decorated with tassels or tails of black horse-hair. At his side he might have worn a broadsword, and in his belt a dagger and pistol. That is the Highland dress. When it was assumed by George IV, at Edinburgh, in 1820, the "garb of old gaul" excited much merriment, which rose to uproarious hilarity when Sir William Curtis, the banker, who was as fat and as vain as the King himself, appeared in similarly preposterous attire. Nobody laughed at the Highland dress nowadays. It is worn indiscriminately by officers in the Highland regiments, by gillies, by affluent English tradesmen who have hired shootings or fishings in Scotland, and by the children of discontented rich people. It is an uncouth and barbarous garb, but we have grown accustomed to it.—*Pall Mall Gazette*.

A REMARKABLE CASE.—Scarcely less astonishing than Dr. Tanner's recent feat of fasting, remarked the N. Y. *Evening Mail*, is the condition of a young lady, daughter of the Mayor of Grambske, a village near Bremen, who is said to have been fast asleep ever since the second week in January with the exception of a few hours of semi-wakefulness at intervals of from six to eight weeks. An interesting account of her extraordinary estate is published in the *Hanover Courier*. It appears that she lies, plunged in a profound slumber and entirely unconscious of all that goes on around her, night and day, reclining on her left side, warmly covered up and with a light gauze spread over her head. Nourishment, chiefly in a liquid form, is daily administered to her, which she swallows without awaking for a second. She is a pretty, slender girl, of a pallid complexion, but she does not lose in weight during her trances of from forty to sixty days, and when awake exhibits a cheerful disposition and an eager desire to perform such small household tasks as her strength enables her to fulfil. Her father is a well-to-do man, who has consulted several eminent medical men in the hope of discovering some remedy for his daughter's abnormal condition, which entails serious inconvenience and constant anxiety upon the other members of his family, but all efforts hitherto made to keep the unlucky girl awake have resulted in total failure.

THE FASTEST TORPEDO BOAT.—The Russian government a few months ago gave orders to a firm at Bristol to construct for it a torpedo boat, 60 ft. in length, 7 ft. in width and 5 ft. in depth, stipulating at the same time that she should make 18 knots per hour on a trial trip before she would be accepted. The boat was finished a few weeks ago, and Mr. Geo. R. Dunell, of England, who is here as the representative of the Russian government in the matter, made a trip in her on Wednesday, September 1st, on Narragansett bay. On a 6-knot run she attained a speed of 19.87 knots, or about 23 statute miles, and she was immediately accepted by Mr. Dunell. An hour later she started for this port and was shipped to Europe on the steamship *Holland*, of the National line. She is said to be 3½ knots better than any torpedo boat of her size built up to the present time.—*Iron Age*.

PROF. CHARLES RAU, archaeologist of the Smithsonian Institution at Washington, has, at the special request of Prof. Leon de Rosny, President, accepted the title of Delegate of the Institution Ethnographique of France. This distinction is conferred in recognition of Prof. Rau's eminent services to ethnographic science. The Institution Ethnographique comprises various societies, one of which has for its object, exclusively, the study of American archaeology and ethnology.

The Color-Blind Scare.

Connecticut is, we believe, the first State to pass a law prescribing certain regulations to be observed by railroad companies in regard to this subject. If all the other States should follow suit, and each of them enact a law as crude, vexatious, unjust and annoying as this pioneer specimen, the skilled ophthalmic experts all over the land may safely count upon having a good time, however it may be with locomotive engineers and others who have rendered long and acceptable service upon our best managed roads. There is sure to be blundering, short-sighted work, when legislators who have no practical and scarcely any correct theoretical knowledge of railroad operation, undertake to remedy supposed defects in the system which in some unaccountable way have escaped the notice of the shrewdest and most capable managers; and the liability to blunder is none the less when the mercenary greed of a selected corps of professional experts is to be satiated at the rate of two dollars a head for the great army of railway employees whose duties require them to have anything to do with the form and color of signals. And so the companies must be taken in hand, and reliable and long-tried engineers who have never had an accident on the road, driven from service because they can't read letters three-eighths of an inch long at a distance of 25 ft., or sort colored worsteds in a scientific manner, or see red and green precisely as some other people do, although they are able to discriminate just as sharply between the two, and be as little liable to confound or mistake one for the other. The logic of facts shows conclusively that the danger from color blindness, about which such a hue-and-cry has been raised, is greatly exaggerated, and that in no single one of the many careful and searching investigations that have been in all the past history of railroads, has the cause of an accident been traced to color-blindness, nor has this particular cause even been suggested or suspected, so far as we have been able to ascertain from the record.—*National Car Builder*.

STEAM DREDGING FOR OYSTERS.—Geo. M. Grave, of Oyster Point, New Haven, has now in process of construction an oyster boat designed for steam dredging. She is 71 ft. long, 17 ft. beam and 6 ft. deep, her engine 30-horse power and her screw propeller 53 inches. The boiler is on board and the work is being pushed as rapidly as possible. There is an over deck from 7 to 9 ft. high made water tight. In the side of this over deck, in a line with the main hatchway, are openings, 6 by 8 ft., which when dredging open inwardly and are hooked to the ceiling. Through these openings the dredging is done by steam, saving the weary "back breaking" that attends dredging in the ordinary sailboat. Forward is the fore-castle in which are berths or bunks for the crew. Directly over this is the pilot house, and back of this the captain's quarters. The expense of running this steamer is for fuel not over \$1 per day, 6 men at \$15 to \$20 per month for each. She will dredge in a day from 700 to 1,000 bushels, taking at each lift 12 or 15 hushels, while the sailing boat at each lift will not get more than a hushel or two at once, and during the day will be doing extremely well if she gathers 40 or 50 bushels.—*Sea World*.

A NEEDED PROTECTION.—It has just come to light that several years ago the Iowa Legislature passed a bill incorporating the Iowa Ministers' Mutual Protective Association, and providing that what personsoever, without regard to age, sex, rank, color or previous condition of servitude, including Indians not taxed, should present any clergyman, of whatever denomination, Catholic or Protestant, be he settled as pastor of a church or employed in any capacity by any religious, educational, publishing or missionary institution or association, or merely lying around loose looking for a church, or bushwhacking through the country as a star evangelist, a so-called pair of embroidered slippers, whereof one slipper should be a number three, C last, embroidered in green and yellow and with a high, slim heel, and the other, its alleged mate, should be a number fourteen, D last, embroidered in red and blue, with no heel whatever, should be deemed guilty of an assault with intent to commit bodily injury, and should be punished by fine or imprisonment, or both, one-half the fine to go to the complainant.—*N. Y. Mail*.

PART of the city of Deadwood, Dak., is claimed by placer miners under the mineral land act, and they want to wash out the foundations of houses, to which the owners of surface plots protest. The case has been decided in favor of the miners in the General Land Office, and the surface owners have appealed to the Secretary of the Interior. Under the law, if the land is more valuable for minerals than agriculture, it can be entered as a mineral land, and this seems to be the case with corner lots at Deadwood.

M. CAMILLE FLAMMARION, the popular French astronomer, who has been making several balloon ascents of late, says that he did not feel any giddiness, but that he felt a vague desire to fling himself out of the car. Although convinced of my immediate death, he says, "I felt a gentle temptation to let myself fall, and my own death became indifferent to me. But happily it is one of those temptations which can be resisted."

INCERSOLL ECLIPSE ROCK DRILLS.

The Most Economical Air Compressors in the Market.

MINERS' HORSE-POWER.

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The Power is mainly built of wrought iron. The hoisting drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending the bucket. The frame of the Power is hoisted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 49 Fremont St., S. F.

INCERSOLL Rock Drill and Air Compressor.

The undersigned having been appointed sole agent for the Pacific coast, will keep always on hand a large stock of the various sizes, together with duplicate parts all of which he will sell at factory prices. The Incersoll is the only Rock Drill now in use on the Coast.

W. BRUCKNER'S

ROASTING FURNACE

AND

Ore Pulverizers.

(Awarded the Premium Gold Medal at Naples, Italy.)

The furnaces are especially adapted for roasting rebellious ores; there are more than fifty in use in Colorado, giving perfect satisfaction.

The Ore Pulverizer is built in different sizes. It is preferable to Stamp Mills because it requires less power and less repairs than Stamps. No extra expense for setting up, and no foundation. Less weight and less cost than stamps. Furnished also in sections for packing.

NOW READY!

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW ON SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Quarto. 234 Illustrations.

By ROBERT GRIMSHAW, Ph.D., M.E.,

Member of the Jury on Wood-working Machinery at Paris Exposition of 1875.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand, saw, mill, jig, drag, circular, cylinder and hand saws, as now and formerly used for cross-cutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, swamping, gunning, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 36 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin.

Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the price is this date made \$2.50, postage paid.

ROBERT GRIMSHAW,

624, 626 and 628 Market Street, Philadelphia

March 10 1880.

A Card from Architects.

The California Architect and Building Review.

Office, No. 240 Montgomery Street, San Francisco, Cal.

It is with pleasure that we publish the following from prominent Architects in this city:

Believing that a journal of its kind is a necessity on this coast, and judging from what has appeared in the "Quarterly Architectural Review," we are led to believe that the CALIFORNIA ARCHITECT AND BUILDING REVIEW will be worthy of generous support and encouragement. We therefore pledge our cordial sympathies, personally, and hope that the enterprise will receive kindly recognition and liberal support from all Architects and Builders and the public generally. (Signed) David Farquharson, Wright & Sanders, S. H. Williams, Thos. J. Welsh, P. Huerns, John Marcus, B. McDougal & Son, Wm. Mosser, Wm. Curlett, Meeker & Banks, W. O. Hoagland, S. & J. Newson, B. Hennrichson.

ORES SAMPLED, TESTED, ASSAYED.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1887.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 156 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, \$3.00 coin, postage free.

Books for Miners and Millmen.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arseniurets, and gold and silver ores generally, with 120 lithographic diagrams. 1887. HALL'S VEGETABLE SICILIAN HAIR RENEVER is a scientific combination of some of the most powerful restorative agents in the vegetable kingdom. It restores gray hair to its original color. It makes the scalp white and clean. It cures dandruff and tumors, and falling out of the hair. It furnishes the nutritive principle by which the hair is nourished and supported. It makes the hair moist, soft and glossy, and is unsurpassed as a hair dressing. It is the most economical preparation ever offered to the public, as its effects remain a long time, making only an occasional application necessary. It is recommended and used by eminent medical men, and officially endorsed by the State Assayer of Massachusetts. The popularity of Hall's Hair Renever has increased with the test of many years, both in this country and in foreign lands, and it is now known and used in all the civilized countries of the world.

FOR SALE BY ALL DEALERS.

Pocket Mining Atlas,

Containing the principal mining districts in the United States. Compiled from the latest official surveys and the most authentic sources by Edwin Bolitho. Sent, post-paid, on receipt of \$1. Address, Dewey & Co., 202 Sansome St., S. F.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omissions of agents.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has now varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for \$3 per (half-yearly) volume. In cloth and either binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus, terms of subscription, etc., and request that they circulate the copy sent.

INVENTORS, and others interested, will receive DEWEY & CO.'S MINING AND SCIENTIFIC PRESS PATENT AGENCY Circular free on application at this office. It contains 42 pages of hints and information about Patents, Patent Laws, Patent Office Regulations, and how to obtain valid patents.

HOW TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

Chew JACKSON'S BEST Sweet Navy Tobacco.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

ANNUAL MEETING.

The regular annual meeting of the stockholders of the Spaulding Gold and Silver Mining Company will be held at the office of the Company, No. 117 Battery street, San Francisco, California, on TUESDAY, the Twelfth (12) day of October, 1880, at the hour of 2 P. M., for the purpose of electing a Board of Directors to serve for the ensuing year, and for the transaction of such other business as may properly come before the meeting. Transfer books will close on Friday, the Eighth (8) day of October, at 12 o'clock M., until after the meeting.

JOHN HEIN, Secretary.

Office—No. 117 Battery street, San Francisco, Cal.

Gover Mining and Milling Company.—Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.

NOTICE.—There are delinquent upon the following described stock, on account of assessment (No. 43), levied on the Eleventh day of August, 1880, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. of Certificate.	No. Shares.	Amt.
Ellis, H. C.	226	250	\$ 50 00
Hulme, Eliza J.	245	500	100 00
James, James.	65	63	12 00
James, Frederick.	381	62	12 40
McAfee, Wm.	200	500	100 00
McAfee, Wm.	201	500	100 00
McAfee, Wm.	202	100	20 00
Miller, W. J., Trustee.	243	1750	350 00
Miller, Eliza J.	391	500	100 00
Morgan, W. S., Trustee.	386	1000	200 00
Morgan, W. S., Trustee.	387	1000	200 00
Morgan, W. S., Trustee.	388	2000	400 00
Oates, Wm.	67	100	20 00
Oates, John.	68	125	25 00
Ream, Charles.	72	50	10 00
Ream, Charles.	73	50	10 00
Ream, Charles.	74	50	10 00
Sanborn, F. G.	385	250	50 00
Skinner, Maria.	384	250	50 00

And in accordance with law, and an order of the Board of Directors, made on the Eleventh day of August, 1880, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of the Company, No. 402 Front street, room 8, San Francisco, Cal., on Monday, the Eleventh day of October, 1880, at the hour of one o'clock P. M. of such day, to pay delinquent assessments thereon, together with costs of advertising and expenses of the sale.

W. O. WILSON, Secretary.

Office—402 Front street, Room 8, San Francisco, Cal.

Techattup Silver and Gold Mining Co. Location of principal place of business, San Francisco, California. Location of works, El Dorado canyon, Lincoln Co., Nevada.

Notice is hereby given that at a meeting of the Trustees, held on the 24th day of August A. D. 1880, an assessment (No. 7) of One Dollar per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, No. 237 First street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 30th day of September, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Wednesday, the 20th day of October, A. D. 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

O. F. MOULTROP, Secretary.

New Book on the Comstock.

The attention of MINING ENGINEERS and EXPERTS
is called to the new work by JOHN A. CHURCH, E. M. Ph.
D., on "The Comstock Lode, Its Formation and History."
This very exhaustive treatise on this famous lode is fully
illustrated with diagrams and colored charts showing sec-
tions, ore bodies, etc., and will be of great interest and per-
manent value for reference. DEWEY & Co., Publishers of
the MINING AND SCIENTIFIC PRESS, are sole agents for the
sale of the work. Mr. E. M. SLEATOR will act as their
agent, and call on Mining Engineers and those interested in
the great lode in this city with a copy of the book for their
inspection.

REVOLVING CYLINDERS AND ORE DRYERS,
Hoisting and Pumping Machinery.

**STEIGER & KERR'S
CONTINUOUS DISCHARGE AND GRINDING PAN.**

This pan is designed to receive ore direct from a rock breaker, and reduce it to the fineness necessary for amalgamation, thus taking the place of the ordinary stamp battery. The cost of this Mill places it within the reach of all; and one point of advantage not to be overlooked is the fact that the cost of erection, which adds so much to the expense of the stamp mill, after it leaves the foundry is, in this case, reduced to a fraction, as the Mill is complete in itself, and requires no expensive foundations, bed logs, battery frames, etc., but can be placed in position in a few hours after it arrives on the ground, without the aid of skilled labor. This simple arrangement, durable as it is simple, is a most important improvement in the working of gold ores, as it enables parties to construct and erect a mill at half the cost of a stamp mill, and with a great saving of time, and size of mill building. Each pan is capable of reducing 10 tons of average ore in 24 hours, the ore being first broken in a rock breaker, small enough to go through a half-inch screen. There is an important point in the action of this Mill, to which we desire to call the attention of miners and millmen. We allude to the grinding and scouring action on the gold before it is discharged. The value of this point cannot be over estimated, and it is not necessary to do more than mention the fact, as it will be at once recognized by all competent millmen who examine the pan in operation, and especially by those who have had to deal with tarnished or rusty gold, as it is commonly called, and which is often encountered in our mines, and which is such a cause of loss. The plan of feeding is the same as in the stamp mill, either an ore feeder or hand feeding being adopted, as may be desired. Parties interested in mining and mills can see the Pan in operation by calling at the OCCIDENTAL FOUNDRY, STEIGER & KERR, 137 First St., S. F.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding homastio and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The beating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

The Strongest, Safest, Most Uniform and Reliable "HIGH EXPLOSIVE" Manufactured on the Coast.

MINERS TESTIFY THAT IT IS FREE FROM OBJECTIONABLE FUMES.

We call the attention of all desiring such a Powder to our various grades, which we are prepared to sell at LOWEST RATES.

No. 1. — Equalling Liquid Nitro-Glycerine in Strength. We recommend this Grade in extremely hard rock, boulders, iron, etc.

No. 2. — Will do the work thoroughly in all but the hardest kinds of rock.

No. 3. — For bench work, pipe-clay, soft and shelly rock, outside work and quarrying.

Single and Triple Force Caps, Fuses of all Grades, Vulcan Powder Thawing Boxes, Batteries and Exploders, For Sale at the Lowest Rates.

VULCAN POWDER COMPANY,

Office, 215 California Street, - - - - - SAN FRANCISCO, CAL.

GIANT POWDER

MANUFACTURED UNDER A NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS.

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive

Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. Triple Force Caps and all Grades of Fuse.

A New Ore Battery.

We illustrate on this page the new Reliance Ore Battery, devised by E. T. Steen, of No. 10 Bush street, this city, and which was on exhibition in running order at the late Mechanics' fair. It is constructed specially for high speed any desired number of blows per minute being possible, a result which cannot be obtained with the ordinary stamp battery when cams and tappets are used.

In this battery each stamp runs from 150 to 400 strokes per minute. Figure 1 shows a general view of the battery; and figure 2 is a section through the air-cushion cylinder. A is the cylinder, B the piston which is welded on to the stamp stem, C, this stamp-stem being provided with the usual stamp and shoe. D is the leather packing through which the stem plays. The small hole, G, in the center of the side of the cylinder is the air inlet. The screw, E, is intended for adjusting the blow, and also allows the cylinder to be lowered as the shoes and dies wear away. The connecting rod, F, connects the device with the eccentric in the driving shaft; this driving shaft being run by a belt in the ordinary way.

As the cylinder, A, is raised by the connecting rod, F, and the air-hole, G, comes above the piston, B, the air in the cylinder below the piston becomes compressed until the stamp is raised. The driving shaft is run rapidly, so there is a momentum given to the stamp, stamp-stem and piston. As the cylinder is pushed down the piston, B, will continue to rise until having passed the hole, G, the air is compressed above sufficiently to stop the ascent of the stamp, and throw it down with great force. In effect there is an elastic air cushion above and below the piston; this air being compressed at each stroke by the momentum given to the stem and piston.

The object of this construction is to do away with cams and tappets and make such a connection between the driving shaft and stamp as will admit of high speed without rigid connections. The stamp will accommodate itself to the amount of ore in the battery, the same as an ordinary stamp mill, while at the same time it is directly connected with its driving shaft.

This battery is quite portable; the weight of all the iron and wood work, except the mortar block, for a battery of two stamps of eight inches diameter, is only 5,400 lbs.; weight of the Victor ore feeder, sold with the battery, 500 lbs. Mr. Steen estimates the capacity of the two stamps driven in this way as equal to that of eight ordinary stamps (the iron work of which would weigh about 16,000 lbs.)—the saving of freight is considerable. It can be run with any kind of power. There is not any jar, as the stems are connected by air cushions as described.

This mill will take rock up to two and a half inches. It is not only a prospecting mill, but suitable for large mines in full work. Three sizes are made, which are sold for \$600 to \$1,200, including a Victor ore feeder, the whole being ready to set up. This will include all the iron and wood work, except the mortar block. Mr. Steen claims that this is very much less liable to get out of order than the common cam mill. Water is run through the shaft and the air-cushion guides to keep them from heating by the rapid motion. This water is then passed to the battery.

MORE ECONOMICAL.—The Utah mine on the Comstock is more economically run. The cost of the east drift on the 1950 level does not exceed \$8 per foot. The water, most of which comes in at the 1150 level, is carried through pipes along the 1350 level, then raised by its own pressure behind to the 1250 level, from which connection is made with the 1500 of Sierra Nevada. It flows along this level and through to the Suto tunnel therefrom. This saves at least \$50 per day in wood.

An exchange says: At Soulshyville the new Williams process for treating rebellious ores is a perfect success, and bids fair to make a revolution in the treatment of rebellious metals. The furnace is in good working order, and the tests have all proved favorable. Won't some one tell us what the Williams process is?

Mining or "Lawing."

We see by late English journals that the Emma Mining Company has made up its mind to give up "lawing" and go mining. In consequence of this resolution the shares, according to quotations in the *Mining World*, have gone from 5 to 30 shillings. The officers of the company have for a long time been conducting proceedings in the courts in a most persevering manner. The suits have not, however, been productive of any great financial results, and the stock kept on going down till it reached a mere nominal value.

P. to be transferred to the new company, for which Mr. P. should receive one-seventh of the shares; all litigation and claims to be put an end to. The meeting was unanimously of opinion such offer ought to be accepted, and considered it a very liberal one, and were much indebted to Baron Grant, through whom it has been brought about. In the result a deputation was appointed to wait upon Mr. McDougal and represent to him the views of the meeting.

The *World* in commenting on the subject says: "It must be admitted that by 'explorations' in the law courts it is possible to gratify the acrimonious feelings born of disappointment, but that so far as any pecuniary result is concerned, the only hope lies in a vigorous devel-

Fig. 1.

STEEN'S RELIANCE ORE BATTERY.

final quotation. That the shareholders believed more could be made out of the mine than in the courts is evidenced by the fact of the rise in price as soon as it was determined to go to work with pick and shovel instead of pen and brief.

At a private meeting of the members of the Stock Exchange, shareholders in the Emma mine, held lately in London, Mr. Gager, on behalf of Mr. Park, the American vendor of the mine, attended and made a long statement setting forth the great value of the mine, and also that Mr. P. (who by telegram stated that he would confirm anything Mr. G. might recommend), in his opinion, would agree to give up the mine with all the new machinery, which is of the most powerful character that America can produce, and capable of sinking 1,000 feet below the lowest of the old workings, and to constitute a new company, with a capital of £700,000, distributing six-sevenths of the shares among the present existing shareholders and debenture-holders, he (Mr. P.) finding £24,000 for working capital, which he agreed to subscribe in shares of the new company at par, and also to find £20,000 in cash to be given to the debenture-holders; the mine now held by Mr.

opment of the mines. Mr. Park believes that such an exploration will be successful, or he is not the man to put down £24,000 for working the property. He knows better, perhaps, than any of the shareholders that the Emma has never been properly developed. What would be done with a mine in this country which had only been worked for 300 ft., and which yet had yielded \$800,000 in silver ore? Why, fresh capital would be at once forthcoming, because it would be argued, and argued on the basis of all mining experience, that a mine that had done so well in the shallow must do far better in the deep. If a mine, either here or in America, should give out at 300 ft., then all mining precedent must be set at defiance, but such a coincidence is unknown in both countries, and therefore it may be taken as a matter almost of certainty that further explorations in the deeper levels will yield results such as would eclipse those formerly experienced when quarterly dividends were wont to be paid. On the spot, too, as already intimated, there exists a vast quantity of most valuable machinery which has been at work on the mine since August 4th."

New Mode of Blasting.

A new method of tunnel or drift driving, invented by Capt. Penrice, now in use at Montecan, and also recently at the St. Gothard tunnel, is worthy of trial here, as it is said to produce wonderful results in point of speed and expense. Capt. Penrice placed four boring-machines of great power on a carriage, and set them to drill holes simultaneously 13 to 16 ft. in depth and 2 in. in diameter. The arrangement of the drive was triangular, three of the holes being placed in a row at the base and one in the apex at the back of the level. The center of the three bottom holes was first charged with dynamite or "Gomme-Gelatine," for three-fourths of its length. This explosive enlarged the hole to 4 inches in diameter, the rock being blown out in fine dust. A second charge, still more powerful, enlarged the hole in the same way to 9 inches, and a third, if necessary, brought it up to 13. The two holes on each side were then charged and fired, and the line of least resistance being towards the long "pocket" formed by the first hole, the sides were crushed in, and a kind of cave formed, extending the whole depth of the holes—about 18 inches high and 6 ft. wide. Then the top hole was fired, and the heading "won." The explosion, in this way, was calculated to form a gallery 5½ ft. wide and 5½ ft. high, sufficient for the working of the machine.

Mr. Taylor, who described this system at the recent annual meeting of the Royal Cornwall Polytechnic Society, said that results of this kind had been obtained in the course of experiments on the system at the Mines de Blanz, when the cost of winning a heading for about 7 ft. 4 in. was about £5 4s., of which the dynamite used cost £4. There was the cost for labor and materials extending over 34 hours, 31 of which were employed in drilling the holes, and 3 in blasting and removing the debris. Capt. Penrice claimed that his machine could win the four holes in two hours; but allowing four, it was estimated that in seven hours 6½ ft. of heading would be won, and in 24 hours 20 ft. Ten ft. was said to be easily bored in 16 to 18 minutes. By the insertion of a small tube in each drill, water was conveyed under pressure to the cutting edges.

Mining Superintendents.

We noticed this week the statement of a Montana correspondent that a mining company of Rochester, N. Y., owning property in the Territory, had never yet made a success, although having good mines. The reasons given for their failures was the inefficiency of their superintendents. First, they sent out to take this responsible position a street contractor; next, a merchant-tailor, and then a drygoods clerk.

With this heavy handicapping it is no wonder the mines did not pay; but the case is by no means, unfortunately, an isolated one. There are many similar results from corresponding causes. It is probable that Eastern mining investors will have to learn all these things by experience, as we "Pacific Coasters" have done, since they will not take our experience. Of course many have learned by this time that it is foolish to expect inexperienced men to take charge of mines. Others, however, believe that with good working miners, any one can "hoss the job" and make a success of the mine. The people that think that way are more apt to put money into the ground than take it out.

An incapable mining superintendent can do more harm and spend more money uselessly in a shorter time than any other individual can hope to do legitimately. One of that kind will demoralize a whole camp. If in charge of a big mine—on which much of the prosperity of a camp depends—his had management not only injures the mine, but the camp also.

In fact, too great care cannot be exercised in the selection of the superintendent of the mine. His position is by far the most important one there is to fill, for upon his shoulders often depends the success of the whole venture.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EWS

Miner's Peak, Tulare County.

Distant View of Mount Whitney—Grand Mountain Scenery.

[Written for the Press by J. W. A. WRIGHT.]

This sketch will give the readers of the PRESS a brief account of the ascent of Miner's peak, in the high Sierra, near Mineral King mining district, Tulare county, with an outline of its surroundings and its relations to more noted peaks and domes which form, in its immediate neighborhood, the highest mountain masses in the United States outside of Alaska.

This huge "saw-tooth" is distinctly seen in the clear day of winter and spring, or any cloudless morning, between daybreak and sunrise, from any point in Tulare and Fresno counties for about a hundred miles along the line of railroad. It is like an immense tent capping the mountains. Its top appears but little, if any, lower than the highest of the numerous peaks that are so clear-cut against the morning horizon, for the reason that peaks really higher are from 1 to 15 miles farther east, or more distant. From Hanford this fine peak is 64 miles in a straight line, about 10° north of east. From the town of Mineral King it is in full view about three miles in a straight line to eastward. Its summit can be reached by several routes, according to the object to be accomplished. By the most direct routes, up the deep and very picturesque gorge known as

Monarch Canyon,

You must travel not less than five or six miles to reach its lofty top. Of this distance you can ride about three miles, if you wish, but you have a trail for little more than the first mile. With a safe guide there is no very precipitous or dangerous climbing such as friend Lsmon eo graphically describes in his ascent of Mount Shasta; but it is tough, wearisome work, riding or walking. This fact can be at once appreciated when you remember that in three miles horizontal distance from town you make a mile or more in perpendicular height; for the townsite being about 7,500 ft. above sea level, the top of

Miner's Peak

is scarcely less than 5,500 or 6,000 ft. higher. Could we have had a good aneroid in that very interesting mountain region, its altitude could be given more definitely, but, much to our regret, we were disappointed in getting one, as we intended. The only means by which we could approximately estimate its height, were: First, comparing it, when on its summit, with Kaweah and other peaks that were known to be 14,000 ft. high and upward; and second, its great elevation above the last trees we passed—*pinus contorta*, or hack-ma-tack. Near Mammoth City these trees disappear at altitudes of 11,000 ft., as we found from barometrical and other measurements last summer. A degree of latitude and more farther south, as Miner's peak is, these pines are likely to flourish even above the altitude of 11,000 ft.

As our party, which made the ascent July 27th last, all agreed that the perpendicular height of the summit above the last timber must be at least 2,000 or 2,500 ft., we concluded that 13,000 or 13,500 ft. make a fair approximation for the altitude of Miner's peak. The entire ascent from Mineral King flat and back is made in from 10 to 12 hours' climbing, allowing an hour or two to spend on the summit and enjoy to the full

The Magnificent Panorama of Mountain Scenery

That is unfolded on every side. My six companions, on the day in question, were all Tulare county men. They were Joe C. Palmer (who served in the Union army during the war under Gen. George S. Evans) and W. B. Wallace, well-known mountaineers and prospectors, with Jacob Rynerson, Wm. D. James, Wm. E. Wild and Spier Jackson, of Visalia.

After an expenditure of muscle and breath and will that none can appreciate until they have tried it, we were all gathered between 3 and 4 p. m. in a cosy little niche on the summit, formed by massive granite elahs. These great rock masses, of almost every form and size, were piled upon each other in utter confusion for the last 1,000 ft. and more in elevation, and the last mile of our rough route. A few moments of rest and the thrilling view of the grand scenery around us soon removed entirely all the feeling of exhaustion and occasional giddiness, with which we were almost overcome at times by the extreme rarity of the atmosphere and the very hard climbing during the last mile among the trackless rocks, and over the coarse yielding sand into which these myriads of granite masses are constantly crumbling, by the action of the elements, without ever seeming to become fewer or smaller.

Immediately around us, within a circuit of four miles, were at least five yawning abysses, with bare, craggy, precipitous sides, and beyond them deeper and more gradual depressions, the bottoms of which lay from 2,000 to 6,000 ft. below us. The town and valley of Mineral King were in full view to westward, nestling

serenely and bewitchingly in the profound calmness of the bright mountain sunshine.

The Impressive Stillness of Death

Reigned supreme everywhere around us; broken only by our own voices and the low, whirling among the rocks of a brisk breeze from the northwest, varied occasionally by the sudden crash and roar of loosened rocks that dashed down some deep chasm near us, and reverberated with startling echoes from numberless precipices. In the deep gorges nearest us, we counted on all sides nine lakes from 200 yards to half a mile long. Their emerald-green waters were usually half concealed with ice and snow, and broad snow patches covered the rocky terraces and ravines around them. Looking far to westward and southwest, over a barren rocky ridge, two or three miles from us, with peaks whose tops were only from 500 to 2,000 ft. below us, we could faintly see the broad Tulare plains, the dark lines of timber along King's, Kaweah and Tule rivers, the lighter-colored spots of our grain fields, the dull-whitish surface of Tulare lake, and the outline of the Coast Range, dimly appearing through the dense haze that enveloped everything in that direction. A mile or two southwest of us were two fine granite peaks but little lower than our point of observation. Their white, precipitous sides, devoid of timber, were separated from us by a wild, deep gorge where one or two picturesque lakes, encased in snow, find an outlet for their waters through the Kern.

On its north side, Miner's peak breaks off into a broad, sheer precipice full 3,000 ft. to the surface of

Cliff Canyon and Columbia Lake.

This rough gorge, with its deep, mysterious-looking lake, covering perhaps more than 100 acres, is simply superb. The whole view for at least three miles in that direction is the wildest of the wild. It is weird, awe-inspiring, fascinating. Your eyes, once turned there, seem riveted to its unique features by an indescribable charm. Beyond the terrace-like bottom of Cliff canyon, scarcely a mile across, is still another gorge, an impenetrable canyon, so narrow, deep and precipitous, that the eye seeks in vain to fathom its depths, as you peer into it, from the apex of Miner's peak. The profound impression made upon you by the misty yet transparent atmosphere, the unmeasured, uncertain depth, and the tomb-like silence of that vast mountain solitude, as you feast the eye upon its varied features, its rock masses of many colors—unclad above except by snow, yet densely covered with pines, and firs and cedars along their bases; all this and much more leave

Indelible Memories.

Second only to those that remain through life, with all who have once looked into Yosemite valley from Glacier point. By common consent of our companions on this excursion, we named its lake Columbia, not only for the usual pleasant associations with the name, but especially in commemoration of the exquisitely beautiful huff or light yellow columbines first found by us in making the ascent at altitudes of about 12,000 ft. These charming flowers and rich purple primroses (*primula*) were found in company around the edges of many granite boulders, blooming luxuriantly in the dry and sterile looking granite sand. By those who have explored this grand canyon more fully than we could then do, I am informed that the water of Columbia lake empties into the Kaweah; while the stream in the deep gorge beyond feeds the Kern.

But now look far eastward beyond the sharp, isolated, hut-like peaks, of which Kaweah peak, three or four miles to northward of us, is the highest, and estimated by our State geologist as more than 14,000 ft. Stretching for miles in that direction, and north and south along the line of drainage of the Kern are the high table lands of that fine river and its many tributaries. This broad, elevated valley is densely and uniformly covered with part of that inexhaustible timber belt that stretches from the sources of the main Kern, on the western slopes of Mt. Williamson, for nearly 70 miles towards Kernville, which is about 55 miles very little east of south from Miner's peak. Due east of us, the main stream is only about 7 miles distant. In its vast forest, but little explored as yet, hunters can find all the deer and bear they want. The streams abound with the finest mountain trout, which camping parties of ladies and gentlemen catch by thousands every summer. The mountain sheep, or "big-head," frequents the higher cliffs. But, see the vast rocky range beyond! What have we there? Why, the very highest of our high Sierra in plain view. There are

Mts. Whitney, Tyndall and Williamson.

Yes, at last we are looking with certainty on those celebrated peaks: In straight lines—as all these distances are given—Mt. Whitney, with its altitude of 15,000 ft., is 16 miles slightly north of east from us. Tyndall, 14,386 ft., is about 7 miles, a little west of north from Whitney; and Williamson, 14,300 ft., with its sharp, minaret-like pinnacles, 1 or 2 miles farther north; that is, about 20 miles northeast of Miner's peak. When we first saw the great summit ridge from the crest of the range we were on, dark clouds were settling around these highest peaks, and a thunder storm raged for an hour or two, though our sky was clear; but it passed away before we descended.

The Form of Mount Whitney,

Thine seen from the west, is so peculiar, and its predominating height is so evident, that it is

easily identified and remembered. Its appearance is that of a half dome. From the base of a much lower dome, to southward—which forms the brow, while Whitney forms the huge Roman nose of an upturned face—there is a gradual curve to northward, where its highest point is. Its northern face appears precipitous, dropping off suddenly in three distinct, regular steps—with the symmetry of a design from some huge, rough-ashler. From the commanding point of Miner's peak any unbiased observer can clearly see that Mount Whitney, as here described, towers far above any neighboring peak, the only peaks approximating its altitude being the high, sharp peaks to northward, known among scientists as Tyndall and Williamson. It is quite probable that one of the last named peaks, or a neighboring one, is the so-called Fisherman's peak—if not Mt. Whitney itself—which several amateur mountain measurers have guessed was possibly higher than the grand peak which has come to be known as Mt. Whitney.

Mt. Brewer, 13,880 Ft.,

A long, narrow peak, shaped somewhat like a chisel, is about 16 miles almost due north from Miner's peak. Six miles north of it is Mt. Gardner (14,000 ft.), and four miles farther north is Mt. King (14,000 ft.). Mt. Silliman, distinctly seen from the Tulare and Fresno plains as a long saw-tooth peak (11,623 ft.), is only about 13 miles from Miner's peak. The ridge running southeast from Silliman, 10 miles to Mt. Kaweah, and thence in a curve northeast 17 miles to Mt. Williamson, forms a huge V, and is part of the boundary line between Tulare and Fresno counties. Beyond it, you are overlooking the various divides drained by King's river. Slightly west of north, 44 miles, is Mt. Goddard, 14,000 ft.—eastward 43 miles, westward 12—on the northern and eastern slopes of which the south fork of San Joaquin river has its sources. In the same direction and 90 miles distant is

Mt. Lyell, 13,217 Ft.,

On whose southeastern and western slopes the main San Joaquin and its north fork rise, while its northern glaciers feed the Merced. To Owen's lake, due east, is 27 miles; to Independence, northeast, is 30; to Mammoth City, 28 miles west of north, is 80 miles; and to San Francisco—northing 90 miles, westing 210—the distance, as the crow flies, is about 225 miles. To the nearest point on Tulare lake southwest is 55 miles; to the crest of the Coast Range mountains beyond it, 90 miles; and following in the same line to the

Nearest Points on the Pacific Ocean,

About 140 miles. These nearest points are Moro Rock in Estero bay, and San Luis Land, nearly 20 miles farther south, in San Luis bay. Slightly north of west, it is 180 miles to the nearest point on Monterey bay. To Santa Monica, due south, is 165 miles. Considering these last figures, coupled with the facts, first, that the top of Miner's peak is about 23 miles above sea-level; second, that many depressions in the intervening Coast Range, from 90 to 100 miles distant, are little more than 3,000 ft. in altitude; third, that from a height of 13,000 ft., the line of vision commands a radius of about 140 miles of the earth's surface; it seems barely possible, that, late on the afternoon of our clearest days, the glistening waves of the Pacific may be seen, if you look southwest from the top of Miner's peak, by their reflection of the rays of the departing sun, especially if the state of the atmosphere will aid by its mirage. Some mountain climbers of that region assert positively that they have seen such sparkling surface beyond the dark outlines of the Coast mountains.

Best Route to Mt. Whitney.

Though Mt. Whitney is but 18 miles in a direct line from the town of Mineral King, it cannot be reached in less distance than 50 miles, and by moderately good trails most of the distance. Ten days should be allowed for the entire trip there and back. You go southeast through Farewell gap, and down the Little Kern to the main river, up the west bank of the latter to a point above a lake covering some 90 acres, and called, as yet, Kern lake. There you cross the main Kern and follow up Whitney creek to our highest mountain. The latter creek you cross on a natural bridge just above its mouth. For most of the way you follow the Hockett trail, between Tule river and Lone Pine. This is the route of all routes from the west to Mt. Whitney and all its curious surroundings.

Hanford, Sept. 22d.

RETURNING PROSPECTORS.—During the past few days a number of prospectors have come into town from various sections after supplies and to exhibit specimens of what they found during the summer campaign. Mike Solney and J. Sullivan came from the vicinity of Mt. Grant in Esmeralda county yesterday. They have two good sized ledges over there which prospect well. The rock contains gold and silver and is in a porphyry formation. They report the country terribly rough but rich in mineral. Two prospectors arrived from the vicinity of Bloody canyon Tuesday forenoon. They have been out there for two months investigating the hills for many miles. They speak in very encouraging terms of the formation. The country is straight up and down, but is interesting and they predict a bright future for the place. A great many men are over there now, but owing to the poor conveniences but little headway is being made in developing claims. Next summer will witness a great change in the whole country around about Homer district. —Bodie Free Press.

Bisbee City, Arizona.

A correspondent of the *Arizona Citizen*, writing from Bisbee, says:

Tombstone has awakened to the stern reality that her eister neighbor may at no distant date be a formidable rival of no mean consideration. So deep an interest have the population of Arizona's brightest prospect taken in Bisbee City that a subscription for direct communication has met the hearty approval of all.

Improvements in the shape of building are retarded because of the difficulty of procuring lumber, and so the different classes of business are at present content to use canvas architecture for shelter. Lots are being graded and sold all down the canyon, even below the smelter, and should water be found by Messrs. Herring & Co., there can now be no doubt of a beautiful and profitable future for this mountain settlement.

The Queen is progressing in her powers of production with every blast. Each full day's work consumes nearly 15 tons of ore, making the round of three shifts (day and night) about 30 tons. Each charge consists of 300 lbs. of ore, 35 lbs. of silica and charcoal and coke to complete it. From the run of a full 24 hours, there is between 4 and 5 tons of ore which, in San Francisco, quotes at \$270. To-day, besides the shipment of 43,000 lbs. now on its way to the Eastern reduction works, there lies 120,000 lbs. on the metal "dump," awaiting teams to freight it to Benson. "Actions speak louder than words." The smelter, under the able management of its inventor, Mr. Lewis Williams, is perfect in the working of ores from the mine. The crucible bottom, made of a mixture of clay, quartz and coke, pulverized, seems too frail to withstand the intense chemical action of the copper upon its surface, and in consequence thereof requires constant attention and occasional replacement. Eventually, all these delays will be avoided, and then can be known the full power of production.

As yet, everything about the mine shows an unlimited quantity of high-grade ore. Opening at different points, it matters not where, always disclose the "welcome green," and at all times during the day visitors may be seen hunting "specimens," which are most generously given by the owners of the mine, Messrs. Martin and Ballard. At night it is a glorious sight to watch the flowing metal as it leaves the furnace spout and passes down the eleg-waste.

Treating Sulphurets.

In treating sulphurets, says the *Nevada Transcript*, it has been the custom for years to first crush the rock in the battery, after which it passes over the silvered coppers, when the free gold is caught, and the sulphurets and sand pass to the shaking tables, or what is still better, Frue concentrators, where the former is collected, and the latter allowed to pass off into the ravines and creeks. The sulphurets are then worked by chlorination. Where the quartz shows free gold instead of sulphurets, this plan of working ore will probably be continued. Where, however, the rock is heavily charged with sulphurets, it has been practically demonstrated that at least two-thirds of the gold, in the shape of infinitesimal particles of sulphurets, are floated off with the sand and water, and are lost. Assays of ore that went as high as \$200 and even \$300 per ton, have yielded not more than from \$30 to \$40 per ton by mill process.

At the Merrifield mine, on Deer creek, a large portion of the ore is heavily impregnated with sulphurets, and, notwithstanding the fact that the rock by fire assay showed its value to be hundreds of dollars per ton, yet after working the quartz in the most approved manner by the old process, including the use of Frue's concentrators, it was found that the average pay of the ore was about \$25 per ton including sulphurets. The owners believing there was a screw loose somewhere, determined to try a new plan. After the rock passed through the batteries and over the plates, it was caught in vate, nothing being allowed to pass off but the water, after which it was taken to the reduction works of the Pioneer Company, on Gold Flat, where it was chlorinated and worked the same as sulphurets. Nine tons of ore of the same quality as that which heretofore paid \$25 per ton, yielded over \$100 per ton—the aggregate amount being nearly \$1,000. They are now satisfied that nearly two-thirds of the gold in the rock was lost by its being carried off with the sediment and water in exceedingly small particles. No more rich sulphurets rock will be worked in the future at the above named mill by the old method. As the ore is brought to the surface it is put in a dump by itself, and will be worked by the chlorine process. Over \$12,000 a year will thus be added to the income of the owners of the Merrifield mine.

THE Copper Knob mining company, of North Carolina, paid a dividend of \$3,000 in New York on Sept. 23d. The capital stock is divided into 300,000 shares of the par value of \$1 each. This is the first dividend, and is probably the smallest one declared by any mining incorporation. It is just one cent per share. But stockholders in California as well as in New York are in a condition to appreciate dividends, no matter how small, provided they are regular and frequent.

MECHANICAL PROGRESS.

The Future of Steel.

J. S. Jeans, Secretary of the British Iron and Steel Institute, lately made the following remarks respecting the subject heading this article: "The more the subject of the manufacture and uses of steel is inquired into, the more does it seem incapable of exhaustion. Great things have been accomplished in the past, but much yet remains in the future. The manufacture of steel is far from finality. Even now some of the leading steel works in France are essaying the production of ingots of 100 tons weight. Steel, indeed, may be compared, in reference to its multifarious uses, with the elephant's trunk, the adaptability of which enables it with equal ease to pick up a needle or pull up a tree. High authorities have expressed the opinion that steel will have the future nearly altogether to itself, displacing copper for fire-boxes, etc., silver for articles of ornament, and lead for its specific purposes, as much as it is superseding iron in respect to utility, economy and endurance. And as it is difficult to set bounds to the ultimate application of steel, so it is impossible to limit the means of its production."

Recent metallurgical progress has indefinitely increased the resources available for the latter purpose. Science has at last found a method of ridding of their deleterious contents the ores of iron heretofore unsuited for the manufacture of steel, and henceforth, if metallurgists of experience are not greatly deceiving themselves, the cheapest and most plentiful area will, by one of the greatest chemical triumphs of the age, be raised to the same rank as the richer and comparatively limited area that have alone been deemed fit for steel manufacture until now. The horizon of the future, therefore, is not bounded by any limitation of the supplies of raw material. Nor is it any more likely to be measured by the uses of steel, for they are multiplying every day, and as the manufacture is cheapened and improved, so will the applications continue to increase. In the track of this movement many changes must follow, and have even already occurred, of which we have been able to take but scant cognizance. The hard and irksome work of the puddler has been superseded by less arduous, and, in the main, by less skilled labor. One of our greatest authorities has calculated to convert fluid cast iron into steel; the labor required is only about one-third of that needed to convert pig metal into wrought iron, while the fuel consumed is only about one-fourth of that formerly used. The economy of coal is, therefore, another important corollary of the advance of steel; and this economy, great though it be in the aggregate, is trifling in comparison with that accomplished through the greater strength and endurance of that which we are fully justified in describing as the metal of the future."

A New Projectile.

Gen. Hutchinson, an officer in the British army proposes, in the last number of *Macmillan's Magazine*, an entirely new form of projectile to meet the novel conditions of penetration necessitated by the monitor-type of war vessels. However modified in details of construction, the warship of the present conforms more and more to the monitor principle, in the submergence of the hull and its protection by means of armored sides sloping at an angle calculated to send projectiles glancing off harmlessly; and the indications are that the war ship of the future will always present a turtle back to the enemy's guns, rather than the high vertical sides of the old style of ships.

Against armor of this sort but little is gained by increasing the weight of projectiles and the range of guns. The cylindrical shot, spirally rotating, may be irresistible when fired against a vertical target; but they are hurled in vain against a ship with no sides to batter.

The projectile proposed by Gen. Hutchinson has a disk-like form and a vertical rotation. Instead of glancing from a flat-armored ship, or from water, such a shot must of necessity maintain its line of motion; and with heavy shot no slope however slight given to armored decks or bottoms could save them from penetration. With a rotation like that of an advancing carriage-wheel the upper edge of the projectile, on striking a ship's bottom, would receive an impulse upward and crash through any double bottom or cellular compartments. With the reverse rotation the lower edge would receive an impulse downward, and the whole momentum of the projectile would be brought to bear like a heavy circular saw upon the deck impinging upon.

The rotation is imparted to the projectile by a "catch" in the barrel of the gun which gives the projectile a twist as it leaves it. No rifling is required, and the entire surfaces of both bore and projectile are smooth with the exception of a slight protuberance—the "catch"—in the former and a corresponding depression in the latter. The projectile simply rolls out of the gun, with great initial velocity, unretarded by rifling or a column of packed air before it, as is the case with ordinary projectiles. A very simple illustration shows the manner in which both gun and projectile is formed and operated. The same projectile, whirling rapidly along the ground, would prove far more destructive to cavalry or infantry than any other projectiles now in use.

A New Mechanical Motion.

There are reports of the discovery and utilization of an entirely "new mechanical motion," by a company styled the New York and London Metal, Wood and Stone Working Company. The object of the device is to cheaply and expeditiously work wood, metal and stone. The agent is described as a perpendicular, reciprocating, rotary, or spiral motion, by which a pair of tools is made, each separately, to revolve horizontally or to raise and fall vertically. The tools, which are of various shapes, according to the material to be worked upon, are thus caused to strike peculiar cutting, turning, or winding blows. These blows, delivered with lightning-like rapidity at the rate of 6,000 to 10,000 per minute, produce certain new and useful results, heretofore unknown and impossible to be effected by any known machinery, and in certain important respects, impossible to be practically accomplished even by the most skilled hand labor. Many classes of useful and ornamental work, hitherto done with painful slowness, at great expense, by skillful workmen, can now be done with great rapidity, beauty and accuracy by apprentices and girls. The machine constructed by this company, while they all embody the same principle, are divided into three classes, each wholly different from the other in size, appearance and arrangement of auxiliary parts from the small metal machine, adapted to do the most delicate and beautiful work on gold, silver, and other metals, to the magnificent three-ton machine, the cutting-head of which moves with majestic and irresistible power across the face of large blocks of granite.

A Queer Locomotive.

The Patterson (N. J.) *Guardian* says that an engine is now in process of construction at the Grant Locomotive Works which, it is thought, will eclipse for speed anything yet built. It will look like an ordinary engine turned upside down. The machinery will be on top of the boiler instead of under it, as usual, and the boiler will hang very low on the wheels. There will be two pairs of driving-wheels, but instead of having them follow each other, one pair will be on top of the other. The rear driving-wheels will be the upper pair, and they will turn in the opposite direction from that in which the engine is going. They will rest upon the rims of the other pair, which will in turn rest on the track. The revolution of the upper pair, by friction, is expected to drive the lower pair, the tires of the latter serving as tracks for the upper ones. It is thought that a good deal greater speed can be got out of the machinery by this construction, and it is expected by the inventor that it will be the fastest locomotive ever made. Practical workmen, however, think it won't go at all. It will look very funny, as it is running through the country, with the upper pair of driving-wheels, five ft. in diameter, revolving up in the air in the wrong direction at a tremendous speed, and the eccentrics, rocking-bars, link-motion and pistons on the top of the boiler.

HOW TO WELD A BROKEN SPRING PLATE.—Get the length and then take the part of broken plate which is easiest to handle and upset it suitable for welding. Make a piece of iron five-eighths of an inch wide, quite thin at one edge, leaving the other about three-eighths of an inch thick, something like a razor blade. Take a welding heat on the part that has been upset and weld the iron across, having the thick end on the point of the plate. Scarf it for welding, upset the other part of plate and scarf it so that when welding, the piece of iron comes between the two steels. In the first heat—it can not be done in one—don't strike too hard at first, and thin down any thick edges of the scarfs. Take a second heat and the result will be, in the hands of an average smith a good sound weld. If the steel is at all fiery do not attempt to weld it. Should there be a hole near the broken place, showing, on being heated, any sign of a flaw, make a new plate. The piece of iron welded between, facilitates the welding, and also makes up for the length lost in jumping.—*London Coach Builder's Journal*.

THE ACTION OF PLUMBAGO.—Friction is the interlocking of the minute elevations and depressions on the bearing surfaces; graphite, which is impalpably fine, packs itself into the depressions of a bearing, raising them to an even surface, and as there are no depressions or elevations there is, as a result, the minimum of friction, which on first appearance seems truly magical. A planing table at the Stevens Institute, was lubricated with sperm oil, and it required then the united force of eight men to move it. When the same table was lubricated with graphite it was moved with ease by a single person, with one hand.

UTILIZING OLD STEEL.—An Englishman named Drake has invented a process of using up old steel in the formation of a new metal which is said to possess extraordinary strength and ductility. The process consists in mixing up old steel with a patent compound, and subjecting the whole to an intense furnace heat, when the particles amalgamate. Steel made on this plan has been sold for \$45 per ton. The process is said to be second in importance only to Bessemer's invention, and it will be especially valuable as finding use for old Bessemer steel rails.

SCIENTIFIC PROGRESS.

Transmitting Sound by Light—A Remarkable Discovery.

Mr. Bell, the well-known inventor of the telephone, has just announced, at the late meeting of the American Association of Science, at Boston, a new and still more remarkable discovery than that which has already made his name famous. His new discovery is nothing less than the production and reproduction of sound by the undulations of light. By the telephone, as is well known, sound is conveyed from one vibrating disk to another by means of a wire connecting the two; and the sound is made still more audible when the connecting wire is charged with a continuous current of electricity. By Mr. Bell's new instrument, which he calls a "photophone," sound is conveyed from one vibrating disk to another by such an unsubstantial thing as a simple ray of light, without any connecting wire whatever. To illustrate, take a telephonic circuit, and remove the connecting wire. Substitute, in place of the ordinary transmitting disk, a flexible mirror of thin mica or glass, in such a position that it may receive light directly from the sun, or from any other source, and have an intervening lens or lenses so placed that the light thus received may be reflected in a straight line to a receiving disk of selenium placed at the opposite termini of the circuit. Now, if the speaker's voice is directed against the back of the transmitting mirror, the mirror will vibrate the same as the transmitting disk of a telephone, and these vibrations produce corresponding undulations in the beam of light reflected by it.

Just here comes in the new discovery by Mr. Bell, that the undulations of the beam of light not only convey to the receiving disk the vibrations of the transmitting disk, but, through the peculiar properties of the selenium, these vibrations are made audible, the same as when connected by the wire of the ordinary telephone; in other words, the beams of light in the photophone take the place of the wire in the telephone.

It has been found that other substances than selenium, when in the form of thin diaphragms, are thus sensitive to the action of light; but none other so much so as to make it practical. Musical tones are more easily produced than any other. Even the light of a candle has been found sufficient for the purpose. Mr. Bell, in his address at the late meeting of the American Association of Science, said: "The fundamental idea, on which rests the possibility of producing speech by the action of light, is the conception of what may be termed as an undulatory beam of light, in contradistinction to a merely intermittent one." He defined an undulatory beam as one that shines continuously upon the selenium receiver, but the intensity of which was subjected to rapid changes, by the constantly varying surface of the transmitting mirror. Thus far the experiments have been conducted over short distances only; but there is every reason to believe that similar results may be obtained as far as a beam of light can be conducted. Speculations in regard to the practical value of this discovery would now be premature; but the whole world waits with impatient curiosity for further developments.

AN ASTRONOMICAL DISCOVERY.—Prof. E. C. Pickering, director of the Harvard observatory, lately made a discovery which is regarded as one of the most important of the century in stellar physics. In the ordinary telescope a star appears as a point of light, brighter, but not larger than when looked at with the naked eye. Prof. Pickering finds that, on placing a prism between the object glass and the eyepiece of his telescope, the light of a star is drawn out into a continuous band. When, however, the telescope with the prism is directed to a planetary nebula, the light is collected into a star-like point without any band, enabling the astronomer to distinguish instantly between a star and a planetary nebula. This principle has already enabled Prof. Pickering to discover several planetary nebulae. On Thursday evening, August 26th, an object was observed which presented the appearance of two star-like points within the band in the modified telescope. It is different from anything heretofore observed in the telescope, and is regarded as an important object for investigation.—*Scientific American*.

NEW USE FOR THE SAND BLAST.—A new use for the sand blast has been found. This is for sharpening old files. The experiment has been successfully tested in railroad machine shops in New England. The apparatus consists of a steam pipe leading from a boiler, and a small hose connecting this pipe with a box filled with fine wet foundry sand. When steam is passed into the pipe the sand is drawn into it and propelled with great force against the object to be cut. The file is held in the blast with the tang towards the operator, and is perfectly and easily sharpened in from two to five minutes, leaving the file in better shape than when recut. Razors and edge tools can be sharpened in the same way.

A New Way of Studying Sounds.

A new and simple way of producing colored rings, which seems capable of some interesting applications, has been recently brought to public notice by M. Guebard. A saucer filled with not very pure mercury is all the apparatus required. Then clear off with a piece of card or paper, the thin pellicles of oxides and dust, breathe on this bright surface, and a magnificent system of colored rings is given by the film of condensed moisture formed thereon. Instead of the four or five "irises" described by Newton, six or seven can be well made out, and the thickness of the film increasing from the border inwards, the order of hues is reversed.

Still hotter effects can be had by dropping volatile substances (as petroleum oil) on the mercury surface, instead of breathing on it; but the most remarkable results are had with condensation. Diluted with ether, this gives pellicles on the mercury, which may be detached (after their thickness and colors have been regulated at will) and transferred to paper. M. Guebard has utilized these effects in the study of the sounds of the voice. Vowel sounds uttered above the moistened mercury surface produce characteristic ring figures, which throw new light on the nature of the vibrations involved. The vibratory state, indeed, for vowel sounds, appears to be often very complex, the figures presenting groups of several ring systems indicating several centers of percussion.

INFLUENCE OF LIGHT ON SIZE OF LEAVES.—M. Ch. Flahault, in the *Annales des Sciences*, brings forward additional observations to support his view that under equal conditions the leaves of plants of the same species are larger in proportion as we go northward, those relatively higher dimensions being due to the duration of light of relatively feeble intensity. In cases where the chlorophyll is formed in the absence of light, it must be formed at the expense of the materials stored up in the tissues. The importance of these reservoirs of nutriment is still greater in the case of flowers. Thus, of hyacinths, both red and blue, M. Flahault found no difference in the color of the flowers grown in the light or in the dark, the color being manufactured from the stores of material in the bulbs.

A PECULIAR OCCURRENCE OF DIAMONDS.—Fouque and Levy note in the *Comptes Rendus* of the French Academy of Sciences a peculiar occurrence of diamonds between Kimberley and Waal, in South Africa, are rocks resembling serpentine and some opals, which are looked upon as the products of metamorphism of younger dolerites and other rocks of the diorite group, similar to those found in the Pyrenees. In thin sections of these opals minute diamonds have been found. They were recognized as such by their power of refractory light and by their hardness.

NEW PLANETARY THEORY.—In recent papers before the French Academy, MM. Gaussin, Faye, Chase and Scobol have discussed various indications of law in the arrangement of the planets and some of their bearings upon the nebular hypotheses of Laplace and Herschel. The indications which were given by Prof. Chase were the closest and most striking, furnishing numerical evidence of a projectile force connecting the solar system with the fixed stars.—*Comptes Rendus*.

AN ELECTRIC SUN.—Lontin has been exhibiting in the building of the Industrial Exhibition in the Champs Elysees, Paris, a circular electric light, formed by four voltaic arches. He uses four carbons placed radially, the two which are in the same diameter being connected with the same pole, so that an arch extends from each of the carbons to each of its neighbors. These four arches unite to form a complete circle and produce a light of extraordinary brilliancy.

PHOSPHORESCENT LIGHTING.—Dr. Phipson takes sulphide of barium, or some other substance which is rendered phosphorescent by the solar rays, and encloses it in a Geissler tube, through which he passes a constant electric current of a feeble but regular intensity. He claims to obtain in this manner a uniform and agreeable light, at a cost lower than that of gas.—*Les Mondes*.

A DELICATE CALIPER.—The pachymeter, lately patented in Vienna, which determines the thickness of paper to the one-thousandth part of an inch, is outdone by the micrometer caliper, now coming into use in this country, which determines the thickness of paper or anything else to the ten-thousandth part of an inch.

LUNAR GEOLOGY.—J. Landerer has submitted to the Paris Academy a work in which he seeks to determine the lithologic character of our satellite. He thinks that the density of the moon, and the angle under which it polarizes the light of the sun, are such as to show that the materials of the surface are analogous to those of the silicate rocks.

COPPER IN PLANTS.—M. Dieulafoy reports the presence of copper in plants which grow on rocks belong to the older geological formations. He says that plants growing in soil formed by the decomposition of primitive rocks contain such quantities of copper that it is possible to detect the copper in one grain of their ash by means of ammonia.

as these facts had been demonstrated, Sept. Jones wrote a full statement of them to Messrs. Watson, La Grange & Gibson, the New York bankers, who are heartily interested in the property, and ask for instructions as to the future course to be followed. They immediately telegraphed J. M. Taylor, the expert who represents them, and who was then looking after some of their Arizona interests, to hasten here and make a careful examination as to the prospects. Mr. Taylor arrived in this city last week, and spent some time in the mine. He went to San Francisco next, saying at the time of departure that he would send full instructions as to what should be done. Sunday evening Sept. Jones received from him a telegram dated at Colfax, saying to suspend all operations at the mine. He is now on his way to New York, where he will call a meeting of stockholders and lay the matter before them. It will then be decided as to whether or no another hundred feet will be sunk.

PLUMAS.

MINING ITEMS.—*Plumas National*, Sept. 25: Lots of mining men coming to Plumas. They are commencing to get on the right track. Thirty tons of rock from the Franklin mine, in Contra Costa, in White Sulphur Springs, yielded 477 per ton. This is exclusive of the sulphur, which are being saved. The Franklin is the mine recently purchased by the Suanville company from the Frenchman, Louis Loe. Another big ditch and gravel mine operation started up lately in the neighborhood of Mohawk. A ditch of 20 miles in length is one of the features, but that is a small matter in the day of gigantic mining enterprises. Parties from San Francisco are looking for some of the big gravel locations in the Clement. The probabilities are strong that a gigantic sale of mining property in this vicinity will be made in a short time, to an Eastern company. It covers some of the best gravel mines in Plumas, and will be a big bonanza for the new owners. Loring & Leavitt's claim in Elzebethown still continues to yield liberally. Surveyors are making a map of the Plumas Water Co.'s property. Flann & Hickman are pulling the Clement tunnel along at the rate of 3 or 4 ft per day. A Huntington quartz mill has been ordered for the Antelope mine in Long valley, on the Reno road.

CHEROKEE.—*Greenville Cor. National*: The Cherokee Co. have re-located and rebuilt the old Kettle mill. The machinery is all modern. It was formerly a small mill, but they have added 4 stamps. As soon as it is completed the company will mill rock from the Kettle and Bellas mines. They have also built a large boarding house and several miners' cabins. A fine chimney of rich rock has been developed in the old Kettle mine, and they will soon start a new shaft, which will go down with the pitch of the ledge. The property looks well, and will soon be a bonanza. The surveyors are booming along as usual at the Green Mountain. They are now working tunnel No. 5, and the ledge ranges from 10 to 14 ft wide, with 100 ft of backs to No. 4 tunnel, and from No. 4 to the surface is 340 ft, making 740 ft of backs from No. 5 to the surface. They are raising an air shaft from No. 5 to No. 4, the raising being up 200 ft now, and a shaft being sunk from No. 4 to the contact with the ledge. The Silver mine, however, has changed hands, and the ground for a new 40-stamp mill broken to-day. The new company intend to have the mill running by the time snow comes.

SAN BERNARDINO.

QUARTZ.—*Riverside Press*, Sept. 24: A. J. Myers and Antonio Atonelo are the owners of a gold claim, at Placerville, 22 miles southeast of Riverside, which promises well. At this surface the ledge is but 6 inches in thickness, but down at a depth of 22 ft the ledge has a width of 2 ft and 3 inches, and the rock grows richer as the shaft goes down. At the present time the rock contains much free gold. The first 4 days of last week 3 men took out and worked in an arastra 2 tons of rock, which yielded \$70, and, during Friday and Saturday, 700 lbs of rock yielded \$47.75.

SIERRA.

A PROSPECT.—*Mountain Messenger*, Sept. 25: The Bradbury boys and others, of Forest City, have struck a prospect in their shaft above Cornish ranch, on the north side of the Meadows, where we can learn that the shaft is about 50 ft and found the bedrock pitching into the hill.

DITCH TUNNEL.—The American Hill Hydraulic M. Co. are at work running a tunnel for a ditch, being afraid to trust the present tunnel for another season. The new tunnel will be about 800 ft long, half of which is already completed.

RECONSTRUCTION.—J. H. Thomas, Mr. Swan, Prof. Black and J. Stewart were examining the gravel leads at Morrilton, Grass Flat and La Porte, the past week, and appeared favorably impressed with those mining localities. This far no sale has been made, but one may be negotiated at any hour.

NEVADA.

WASHOE DISTRICT.

UTAH.—*Gold Hill News*, Sept. 20: The incline has been sunk a total distance of 20 ft below the 2150 level, and in hard rock. The east drift on the 1950 level is 320 ft in length, and has its face in softer vein matter. The drift will be continued, unless too heavy a flow of water is encountered, until it explores the formation in that direction to where any change in the formation is found.

COPPER CO.—Cutting down the connection south of mine No. 1, on the 2500 level, to create a gangway through to the Ophir shaft, so that the debris of the mine can be run to that shaft and relieve the Union shaft, that work on the south compartment may be expedited. This morning the face of crescent No. 1 is in better quartz and gives promise of ore.

THE OPHIR.—The drift toward the C. & C. shaft, on the 2500 level, is making excellent progress, and the north-east drift on that level will, during the week, connect with the Joint Mexican east crescent and give needed ventilation.

SIERRA NEVADA.—The incline raise from the 2300 level progresses as usual; total length, 130 ft. The east raise is up 35 ft and is without particular change. The formation has been the same as before.

C. N. S. SHAFT.—Running the pumps regularly and getting a fresh supply of water from the Hale & Norcross. The station on the 2400 level for the new hydraulic pumps is nearly completed, 60 of the 65 ft in length having been made. This station is 20 ft wide and 10 ft high. The foundations on the surface will be completed this week.

ALTA.—Crescent No. 1, 2500 level, is in 40 ft, and crescent No. 2 is in 54 ft. These crescents will be continued as far as possible without danger of flooding the mine, and when indications of water are seen the diamond drill will be used.

OVERMAN.—The winze from the 1900 level has attained a depth of 174 ft, and no increase of water has been struck. The formation continues hard, and contains large quantities of pyrites.

COS. VIRGINIA.—The Joint Best & Belcher winze is making rapid progress below the 2000 level. The yield of the mine remains unchanged.

CALIFORNIA.—The north drift on the 2300 level, to connect with Ophir and complete the thoroughfare between the C. & C. and Union shafts, is averaging 3 ft per day. The yield of the mine remains unchanged.

SILVER HILL.—Some good ore in streaks has been encountered in the south crescent on the 1300 level. The north drift on this level is making 5 ft per day.

LEVATHAN.—A station will be opened at the 850 level, and a crescent run through the ledge to the east wall.

HALE & NORCROSS.—The drift on the 2400 level has been started for driving that tunnel, and preparations are making for following up the hole by the crescent.

BESTON COS.—Work in the north drift, 1850 level, has been stopped and the men put to work on the 2050 level.

BRISTOL DISTRICT.

MILWAUKEE.—*Ploche Record*, Sept. 25: Arrangements have been made by John B. McGee with the New York stockholders of the Hillside company whereby the indebtedness of that company will be liquidated and the corporation placed upon a sound financial footing. This will be glad news to all. The Hillside is now looking well, and Manager Howell is pushing developments ahead with vigor. On the 6th level east, nearly 500 ft from the incline, they are drifting through a large ledge of spar and iron, carrying from 2 to 3 ft of good ore on the footwall. Still standing on the 3d and 4th levels west, and taking out some fine-looking ore. The furnace, upon the arrival of the new front, started up last Wednesday, with an abundance of coal and ore.

BRISTOL.—The Bristol company is sinking a new well, and after 200 ft in depth is attained, will apply the artesian well apparatus and put it down to the depth of 700 ft. They are now working 3 shifts, making 4 ft a day. During the week the Bristol company shipped, through Wells, Fargo & Co., 2 bars of fine bullion. One bar was worth \$2,169.05, the other \$1,614.89. This is the first shipment of the kind.

TEQUEST.—The Tequest, on the southwest line of the Hillside, is showing up a large body of yellow carbonate, with assays running as high as \$375 and \$362 per ton.

COLUMBUS DISTRICT.

SOUTH PLUMAS.—*Esmeralda Herald*, Sept. 25: This mine owned by S. C. Barnes and Peter Gaffney, and joining the Mt. Diablo mine to the south, bids fair to become as rich and famous as its world-renowned neighbor. A shaft has been sunk 14 ft, at which depth a ledge has been struck 8 ft in width, showing pure horn silver in goodly quantity. The discovery is an important one.

ESMERALDA DISTRICT.

GRAND TRUNK.—*Esmeralda Herald*, Sept. 25: The tunnel has been extended south into Middle hill, cutting 3 veins of high-grade ore. A crosscut was run from the end of the tunnel east 260 ft, passing through a fissure over 150 ft in width, showing a large quantity of low-grade ore. A winze is now being sunk on one of the rich ledges near the mouth of the tunnel, and is down 40 ft. The ledge at this depth is 13 ft in width, 13 inches of which on the main shaft is visible, and will yield up in the hundreds of dollars. This streak of high-grade ore increases in width as they go down.

REAL DEL MONTE.—A well-marked line of separation was in the shaft on the 15th, dipping to the southeast, which showed considerable favorable-looking quartz, and from which was a slight increase of water. The depth attained in the shaft last night was 790 ft. At the 800 level a station will be put. From this point operations will begin, and the country explored in all directions.

MILL TO START.—W. H. Bull has been at work for the past 2 weeks repairing the little quartz mill, and informs us that everything will be in readiness and the mill will be started next Monday or Tuesday. There are several lots of 2 to 10 tons of first-class ore to be run through and a large quantity of second-class ore to be worked. Bull & Groh have 10 tons that will mill not less than \$500 per ton. Lots that will average \$30, of which there is a great amount, cannot be worked in this mill, and will be thrown aside until a first-class mill is put up.

PIOCHE DISTRICT.

BULLIONVILLE MINE.—*Ploche Record*, Sept. 23: Work is still continued vigorously on this mine. The sinking of the main shaft being the principal work, which has been sunk to a depth of 50 ft, with stringers of ore coming in as work progresses. The work of sinking is getting easier, owing to the character of ore changing, and the owners of this mine are confident that they have a bonanza in the near future.

ARIZONA.

MINERAL CREEK.—*Chronicle*, Sept. 19: Mr. S. R. Sands, from Mineral Creek, came in last week and reports mining affairs as flourishing in that district. He is engaged in sinking on the Transfer and No. 1, two claims about 4 miles north from Hoyt's camp, where ledge veins were located by Mr. Sands in 1877, and give every indication of permanency and richness. Sufficient work has not been done on the claims to establish their extent, but the owner feels confident of their merit. Width of ledge is 4 ft, and the ore carries equal proportions of gold and silver. Prospectors are plentiful in that vicinity.

MINERAL CREEK MINE.—As this district is attractive to investors, the present information concerning the operations of the Mineral Creek M. Co. I thought it ought of place to give you some information concerning the district. The Mineral Creek M. Co. is employing some 40 men at the mill and mine. The grades and roads are all completed and the construction of the mill commenced. They expect to have the mill ready for receiving ore in 40 days. The ore taken from the ledge in all openings gives assays that are quite pleasing to the officers of the company. There are many other claims now opening in the district that promise to develop into valuable mines.

FRIA VIEW.—*Miner*, Sept. 25: W. M. Haugah, of Bel Rock or Big Bug, called on us to-day, stating that he had purchased the Fair View mine, and was having the same thoroughly prospected. From a quantity of fourth-class ore treated at the Fria furnace, a satisfactory result was obtained. The ore seems to be worth all the way from \$200 to \$750 per ton.

ALBERT LEE.—*Silver Belt*, Sept. 18: The Albert Lee is located on a bold ledge, which shows at intervals for 8 locations, or 12,000 ft. There are several prospect holes on the property, all of which show ore, and at some of them are quite respectable dumps. There is a shaft down 36 ft, and the ore is quite rich. The shaft only the hanging out shows. The country rock is quartzized. There are about 70 tons of ore on the dump. The gentlemen who own this mine, Messrs Lee & Brecken, intend to dispose of the property they own in the southern part of the Territory and use the proceeds in the developments of this mine.

COLORADO.

GOLD.—*Register-Courier*, Sept. 24: Messrs. Harrington & Moller shipped \$90,390 to-day in miscellaneous lots of gold bullion. This banking firm are purchasing large quantities of gold, for the most part in miscellaneous lots.

NEW STAMP MILL.—The Hidden Treasure M. Co. is about letting a contract for the construction of a stone mill building below their present 20-stamp mill on North Creek creek, and its dimensions will be 90x104 ft. The new site selected will give them at least 40 ft fall. It is the intention to put in a turbine wheel of a capacity of 75 stamps, 50 of which will be placed in position this fall.

SPLENDID MILL RETURN.—Mention was made some days ago that Messrs. Richards, Steele & Co. had struck pay in the lower shaft of the Jones mine, Nevada district. This was the ore of E. Randolph, this mine, Nevada district, which yielded 24 ounces and 13 pennyweights of gold for the lot of ore treated, equaling nearly 9 ounces gold per cord.

FURTHER DEVELOPMENT.—It is rumored on the streets of Central to-day that the Lacrosse M. Co. have let a contract for driving that tunnel, and preparations are making for following up the hole by the crescent.

SILVER MOUNTAIN.—On the Fanny lode, contractors have just completed sinking a lift of 80 ft in the bottom of the incline, giving a greater depth of 190 ft. Levels both ways have been started from the bottom of the main shaft. The crevice material at this point carries considerable ore, but in scattered quantities. The Cyclops is improving all along the line of the vein being worked.

IDAHO TUNNEL STRIKE.—*Courier*, Sept. 24: In our last we noticed a strike that had been made at the breast of the Idaho tunnel, of a fine body of ore. Mr. G. M. Henty visited the tunnel last Monday, and from the fact that the ore vein is about 6 inches thick and solid, carrying a large percentage of gray copper and closely resembling the ore of the Tropic mine, of which it is believed to be the extension. It has been located at the surface

under the name of the Surprise lode, and should it prove to be as good as the Tropic the company is already paid for sinking the tunnel to it. The tunnel is now in 613 ft, and has cut 10 ledges and spurs, all of which look encouraging, and several show proof of broad, strong fissures.

IDAHO.

PANAMINT MINE.—*Idaho World*, Sept. 24: The Panamint mine, at Banner, is rolling out rock at a lively rate. The force of men has been increased lately, and the Elmina mill will start up on the ore. The mill never worked better than at present.

JIM CRAW came in last Monday from Copeland and returned on Wednesday. He says 8 men are engaged at placer mining in that place, and will be through for the season the latter part of next month.

The Cluster mill, at Bonanza, will be ready to run about Nov. 1st. It will be 90 ft high, with 5 stories. It has a capacity for 40 stamps, but will start up with 25.

A shaft is being sunk on the Big Creeples, at Banner, and owned by the Elmina company. Very rich ore is now being taken out.

NINETEEN tons of ore from the Washington, the east extension of the Sub Rosa, were crushed this week in the Sub Rosa mill, and went about \$50 per ton.

GIBBONVILLE.—*Idaho Miner*, Sept. 24: Gibbonville, Idaho, across from the head of Blitter Root, has been a self-supporting camp from the start. Several arastras and 1 or 2 mills are now at work there in the reduction of gold ore, and all have paid from the very first shovelful of ore reduced. The lodes have paid their own development from the first blow of the pick struck on the croppings, and in some instances a handsome surplus besides in the way of dividends.

The new mine is now at the end of the A. T. & S. F. R. E., and will be shipped to this place, about 100 miles, the old mill at the reduction works on the Mimbre. We learn that the mill and fixtures weigh about 100,000 lbs, and is one of the most complete mills in the United States. The McGregor mine has of late been turning out some very fine ore, and in paying quantities. Several lessees on this mine are doing well. The Commercial, which lies contiguous to an area between the McGregor and Queen, has also been giving good returns. The other mines of the camp are turning out their usual quota of rich ore. The Meredith & Allman mill, now belonging to the Mimbre company, will for a while run on custom ore.

WICKES. In Jefferson county, is another most promising camp, and an inviting field for the prospector. Mr. Chas. B. Finn, of Butte, who has recently returned from a visit to Wickes, declares that it is one of the healthiest and most hopeful activity. Men are in demand, and labor is to be had without even the asking. The new 50-ton water jacket furnace will make its first run in about 2 weeks, when the industrial importance of the camp will be vastly increased, its bullion product also. The hills about Wickes have been very imperfectly prospected. To the industrious searcher for hidden treasure they hold out a promise equalled by very few other localities, even in matchless Montana.

BAY HORSE.—*Cor. Salt Lake Tribune*, Sept. 24: Capt. Rustin is vibrating around in the vicinity of Clayton City and Squaw creek, and will have his smelter ready to run in about 6 weeks. His mines all look well. The Rams Horn is the boss and is furnishing the smelter about 10 tons per day, and all the other mines along the Bay Horse mineral belt are looking well and producing ore. The Idaho Co.'s smelter on Bay Horse started up on the 15th, on Bay Horse ores, chiefly Rams Horn, and without metallic or any other lead, except what was in the ore. The first bar of bullion assayed 785 ounces of silver per ton. It is now running very smooth and giving perfect satisfaction to the owners. The bullion runs in silver up to the present date from 100 to 1,100 ounces of silver per ton, and the slags show from 1½ to 6 ounces silver per ton.

MONTANA.

ARIZONA.—*Atlantic*, Sept. 22: The immense belt of silver ore in the Argenta district is but 15 miles from Dillon. We may now expect to see the smelter there resume business, enlarge its capacity and stimulate active operations. The lodes and quality of ores are of unquestionable richness, and new capital will not be long in finding this wealth.

COL. BURELL was at Terminus Thursday. He has the Elk Horn mines, in this county, bonded, and it is reported that he is making some good clean-ups.

Four miles from Willis station several parties have lately struck rich silver mines, the ledges running 2 ft wide and assaying an average of \$150 per ton. These discoveries are in the west side of McCarthy peak, only 3 miles from the grade of the U. & N. R. R., and but 10 miles north of Dillon.

LATHROP DUNN, late of the Alice company, left for San Francisco, Saturday, to spend the winter. He thinks that Butte is destined to become the greatest and most permanent mining camp in all the West.

GLENNDALE.—*Cor. Helena Independent*, Sept. 25: The mine and works of the Helena mining and smelting company are running uninterruptedly. Every day teams are loading with bullion and matte for the Terminus. The company gives employment to upwards of 700 men at their mines at Lion Mountain and at the iron mines at Soap gulch, and at the works here. Rumor says the proposed sale of the company's property will be effected within 60 days. Quite a number of our mechanics and experienced workmen at the smelter have come to Wickes in the past 2 months. No doubt in another season Wickes will be an equal, but I hardly think a superior bullion-producing camp to this.

DRUM LUMMON.—Silver Creek Cor. *Helena Independent*, Sept. 25: Years of patient work in the prospect field have at last rewarded Tom Cruise by the discovery of the Drum Lummon, which, by the promising indications of the magnificent 60-ft lode do not fail, will be in another year the richest mining property in the Territory. Mr. Cruise and all of his employees keep reticent concerning the amount and quality of the ore taken out. The shaft is on the mountain back of the mill, which, with its 5 stamps, is crushing out, day by day and night by night, twice the amount of wealth to the capital invested than is turned out by any other mine in Montana. Numerous prospect holes are seeking extensions of Drum Lummon, but none have struck it yet.

BUTTE NOTES.—*Miner*, Sept. 24: The mines of Butte continue to show a steady improvement in the quantity and richness of the ores produced. A new body of exceedingly rich silver-copper ore has been struck in the drift running west from the main shaft of the Bell. An important strike of silver is now being constructed on the Mountain Boy. The ore much resembles that of the Anselmo, and will assay over 200 ounces. Careful estimates of the value of the bullion, ore and matte shipped from Butte place the amount at \$50,000 per week. There is no doubt that the production for the present year will reach \$2,000,000. Dounel, Clark & Larabee yesterday shipped gold dust valued at \$130,000. On Wednesday the Alice company shipped 600 lbs of bullion valued at \$10,000.

STRENGTH AT THE COPPER SMELTER.—On Thursday, at a preliminary trial of the machinery lately put in at the smelter of the Montana copper company, everything worked satisfactorily. The boilers were tested and found to be sound, and everything shown to be in excellent running order. It is expected that the smelting of ore will begin in about 2 weeks. An air shaft is now being constructed from the Colusa mine to the works, a distance of 1,640 ft. The cars will probably be propelled by steam power. By this means the 5,000 tons of concentrating ore on the dump, and the vast deposits of first and second-class ore opened up in the main level, will be conveyed to the smelter, and the heavy expense of wagon transportation entirely saved.

ANSELMO.—During the past week 40 tons of first-class ore have been shipped to the smelter, leaving 150 tons of second-class 80-ounce ore on the dump.

ALICE.—In the upper levels considerable work is being done and the different workings are being put in shape to insure a heavy production when the reducing facilities of the company are perfected. The mill is now constantly getting, and 4,000 tons of ore have accumulated at the new mill, which, from present indications, will be over-supplied in the future equally as much as the 20 stamps have been in the past.

MAGNA CHARTA.—Recent development on this mammoth ledge are of a very encouraging nature. The double-compartment shaft is being sunk as expeditiously as possible, and has reached a depth of 100 ft. It has thus far passed through 2 strata of ore, the one struck yesterday assaying 126 ounces.

GRAY ROCK.—As soon as the mill succeeds in crushing the ore now on hand, the extraction of ore will be resumed

in the west shaft, where several thousand tons are in sight between the 2 levels.

BUTTE.—During the past week an important discovery has been made in the whim shaft, between which and the middle shaft it was supposed the only rich sheet of ore in the mine existed. At a depth of 90 ft, however, a crosscut north, 6 ft to the footwall and a drift east 12 ft, developed the presence of another sheet approaching in richness the sheet which has yielded so largely of high-grade base ore. The new ore body is 2 ft wide; it carries 40% of copper and between 200 and 300 ounces in silver.

NEW MEXICO.

TRES HERMANOS.—*Grant County Herald*, Sept. 22: A. R. Bove brings in some very rich-looking specimens of gray carbonate of lead carrying silver, fair samples of the ore of Tres Hermanos district. There are now about 15 miners at work there, and all express themselves as highly gratified with the prospect. About 100 locations of ore have been made in all, but the principal mines in the district are the Astor, Hancock, Garfield, Chinchault, Hiawatha and Crockett. Many who have gone to Tres Hermanos for the purpose of working their claims, have left through fear of Indians, as the camp is liable to be attacked at any moment. As soon as the present troubles are ended, there can be no doubt that miners and prospectors will flock in from all directions.

GRANDTOWN.—Our mining interests are progressing very satisfactorily. The Mimbre mining company has just learned that their hoisting machinery will be here within a day or so. It will be only a few days until they will have it in place, when the work of sinking some of their shafts on the Nalad Queen will commence in earnest. Their new mine is now at the end of the A. T. & S. F. R. E., and will be shipped to this place, about 100 miles, the old mill at the reduction works on the Mimbre. We learn that the mill and fixtures weigh about 100,000 lbs, and is one of the most complete mills in the United States. The McGregor mine has of late been turning out some very fine ore, and in paying quantities. Several lessees on this mine are doing well. The Commercial, which lies contiguous to an area between the McGregor and Queen, has also been giving good returns. The other mines of the camp are turning out their usual quota of rich ore. The Meredith & Allman mill, now belonging to the Mimbre company, will for a while run on custom ore.

OREGON.

TIM MAMMOTH MINE.—*Beckroth Democrat*, Sept. 22: This mine, about 8 miles southwest of Port Sunlight, and about 7 miles southeast of the Monumental mine, will again begin operations to-day. It is located in the center of a large and rich mineral belt of both gold and silver. The ledge at present is about 16 ft wide, running in a southeast and northwest course pitching at an angle of 70°, between walls of granite and slate. The owners will immediately sink, raise tubs and otherwise operate to fully develop the mine. Mr. W. T. Nelson will superintend the workings of the mine, and Mr. E. D. Browne, engineer.

INYO.

HOMER DISTRICT ITEMS.—*Bodie Free Press*, Sept. 24: They are still getting rich rock from the Josie Green. We are told of a big strike on Green creek, on the northwest slope of Castle Peak. Messrs. How & Travis are having built two arastras, under the direction of J. W. E. Towns. They have about 12 tons of good rock out at the Collamer mine, and the owners propose to have it milled as soon as facilities offer. The Lake Mary mine, which has been located by J. W. E. Towns, who will immediately construct two large arastras, to be run by a hurdy-gurdy wheel. Work on the May Lady mill progresses slowly. The mortar-blocks are set and the battery frame is up, but work in general on the structure is retarded by the scarcity of lumber. We are informed that the usage above the Homer mine will soon start a tunnel just above Mill creek which will cut through the ledge 1,500 ft, using machine drills and running the compressors by water power, which is practically unlimited in that locality. Thos. Condon and Geo. Esh have been at work stripping the Young America ledge during the past week, and are making a good showing. The quartz prospects well.

UTAH.

SILVER CLIFF DISTRICT.—*Prospect*, Sept. 17: The Fannie lode is working a diamond drill, and producing gray copper. The Lumber City and Silver Cliff mining company have commenced work on their Plattsburg claim. Work has been resumed on the First Venture, next claim east of the Silver Cliff, and the new shaft makes a fine showing. The Alta Verde company received, and sent to the mine, the new 20-horse engine ordered by Col. Montgomery of Esmeralda & Davis, Denver. As soon as Messrs. Robbins & Dyer complete their new mill, it will be employed in treating the ore which is now accumulating on the dump of the Horn Silver No. 2. All the heavy machinery for the Robbins & Dyer mill is in place, and the balance of it as soon as the amalgamating pans are in the place the mill will be started. The excavation for the new Silver Cliff mill is progressing rapidly. A large number of men are employed and the work of construction will be pushed to a speedy completion. On the California, which crosses the Silver Horn, a 3-inch "ray streak" of high grade ore was uncovered, at 40 ft from the surface, all of which is being hoisted to the mill. It seems to be conceded that the California vein crosses the Jennie and Mattie claim, which lies just east of it, and in close proximity thereto, which has stimulated the owners to renewed efforts in search of the hidden bonanza within their own surface boundaries. Garrison & Cline will resume work on the Golden Gate as soon as their power hoister can be completed. In their intention to go on down to 150 ft, the owners to their discovery shaft. The new mill of Carter, Cooper & Co., in Burnt Gulch, is progressing finely. It is situated about 26 miles from the Cliff, and is built especially for the ores in North and South Crestone, Cottonwood and Burnt Gulch. It is a 3-story frame building, the frame work having already been placed in position. We understand that there are now 150 tons of material on the coast to their discovery shaft. The new mill of Carter, Cooper & Co., in Burnt Gulch, is progressing finely. It is situated about 26 miles from the Cliff, and is built especially for the ores in North and South Crestone, Cottonwood and Burnt Gulch. Paper, and How it is Made.

No article is more common than paper in its multifarious forms, and yet how many of our readers are familiar with the various materials which enter into its composition or of the process of its manufacture? We have summarized an interesting history of the valuable industry from the Boston *Journal of Commerce*, one of the most intelligent of our eastern journals. The antiquity of paper manufacture is excelled by few other products, Chinese historians carrying it back into the twilight of our history. It was first introduced into England about the close of the 15th century, and into this country near the close of the 17th century—the first attempt having been made at Germantown, Pa., in 1693. The materials from which paper is produced are numerous and various, but wholly of vegetable origin—neither wood nor hair being capable of reduction to fibrous pulp, an essential condition in the manufacture of paper. The most common materials are linen and cotton rags, straw, the leaves and stalks of the okra plant, jute stalks, manila, wood fiber, the hulls of cotton seeds, etc. No substance, however, equals linn rags, out of which the finest and toughest paper is made. Next in value are cotton rags, from which the best writing paper is made. In the manufacture of paper great care must be taken in the selection of the material as well as in every process.

The rags are gathered from all parts of the country and arrive at the mill in bags, a part of the stock, perhaps, coming in pressed bales from over the sea. The first process is sorting, after which the rags are cut by means of a fixed blade in a bench, like a short upturned scythe, the operator picking them up by handfuls and drawing them across the edge of the blade. A second sorting, for the removal of buttons, hooks and eyes, and hard seams, follows, and the rags are then dusted. The duster is a large cylinder, the surface of which is of fine woven wire, inside of which is a shaft carrying arms set around it in a spiral form, and revolving at a higher rate of speed than the cylinder. This difference in speed gives the rags a thorough stirring, while the spiral arrangement of the arms facilitates their exit. White paper can be made from colored as well as from white rags, both the dirt and the color being removed by hoiling the rags in lime water. The rags are placed in a large rotating boiler mounted on journals and driven by gearing. Steam is admitted through the hollow journal and kept at a pressure of 45 to 60 lbs., representing a heat ranging from 292° to 308°. Lime water is mixed with the rags, and the boiler is set in motion. A charge requires from 8 to 12 hours boiling. Even this severe test does not fully purify the rags, and they are next passed through an "engine." A brief description of this apparatus will be necessary for the uninitiated. It is a tank of oval form, the walls or sides rising 2½ ft. from the floor. This is partially divided longitudinally by a straight upright partition, not extending to the ends, however, but leaving a space between its ends and the tank's sides, of a width corresponding to that between the sides of the partition and those of the tank. On one side of this partition, across the center of the tank, is a toothed drum, the teeth or blades of which alternate with fixed teeth at the bottom. These teeth tear the rags to tatters, but without destroying the fiber. A stream of water is constantly passing through the tank, and is constantly removed. This is done by a wheel of fine wire netting that revolves on the side opposite the toothed drum, taking up the mass, but detaining the pulp, the water running off through the shaft of the wheel, which is hollow. Thus the water is used only while making a single passage around the tank, the current being produced and maintained by the rotary movement of the heater or clearer. The coarse pulp which comes from this cleansing engine is technically known as "half stuff," which is again submitted to the action of another engine for still further cleansing. The material is next mixed with chloride of lime and passed through the "beating engine." It is then heaped upon drainers, and looks like a mass of half-melted snow. This white, however, is a dead white, having no brilliancy. To receive this quality it must literally be colored. As the laundress blues her clothes to make them whiter, so must the paper stuff be blueed, and when so tinted it has that same quality of whiteness as wind-driven snow, which always shows a bluish tinge. This is quite different, however, from the blue writing paper which is the favorite tint in the Southern States and in England, that is really blue paper, and is produced by ultramarine, which in the form of powder is mixed with the "half stuff" just before the final beating. Our usual white paper is merely tinted sufficiently to remove the dead, yellow, lusterless appearance of absolute whiteness.

After passing through these processes the material is apparently a thin, milky fluid, having no trace to the eyes of any fibrous quality. Formerly paper was formed by hand, the workman dipping a rectangular sieve into the fluid pulp and depositing the sheet of pulp on a piece of felt to dry. Very little paper is made so now, the Fourdrinier machine having taken the place of the hand of the workman. This machine is a marvelous production of skill; it is almost wholly automatic, and does its work with absolute exactness. A brief account of its work will assist in its comprehension. Some of these machines are not less than 6 ft. wide and 75 ft. long, requiring a building by itself,

and making a sheet of paper over 5 ft. in width. The pulp is pumped into an elevated tank, from which it is delivered to the machine through an adjustable gate opening from a reservoir. The amount of pulp fed to the machine regulates and determines the weight of the paper, and of course it must be governed absolutely and exactly, the speed of the machine being constant. The pulp flows on to a roller, which deposits it on an endless apron of fine woven wire, which has a constantly jarring motion, tending to shake out the water and aid in the homogeneous union of the particles. Thick rubber straps on each side of the endless apron determine the width of the sheet. Passing between rollers which compress it, the sheet of pulp goes over perforated boxes from which the air is exhausted by a pump, and much of the remaining moisture is driven out by atmospheric pressure. A bath of liquid glue gives a proper sizing to the sheet after it is fully dried by cylinders heated by steam. The sheets, dampened by glue, are taken to a drying room, from whence, all wrinkled, they are submitted to a calendar consisting of a stand of rolls, three of chilled iron and two of paper. These latter are made of manila paper cut in disks, with a hole for the axis or shaft, and compressed by hydraulic pressure. When turned and finished, these paper rolls are as smooth and almost as hard as iron, presenting a highly finished surface. The sheets are then trimmed by a machine suggestive of the guillotine, and ruled. The pens used on the ruling machines are of peculiar form, made of sheet brass and fed with ink by a wick.

Book paper is made of old paper entirely, and the processes are similar to those for making paper from rags, except that they are not so long continued. "Juted" is used for making coarse paper, such as is used extensively for flour bags, for which it is well adapted, being very tenacious of fiber. One of these bags holds a quarter of a barrel of flour, 49 lbs. Jute stalks are imported from Calcutta, and are the same material from which gunny cloth and bags are made. The stalks, which are usually 10 to 14 inches long, pass through a rotary cutter, with stationary knives and knives set in a cylinder, by which they are torn to coarse threads. A hoiling under steam pressure in a rotary boiler, with lime, follows, and the mass is heaped and allowed to "sweat" a few days. Then the material is passed through the cleansing engine, is bleached with chloride of lime, and sized with resin and washing soda. The after machinery is similar to that used on writing paper. Fine wrapping paper and envelope paper are made from old manila rope, and paper for collars is made from cotton rags; and in both cases the processes are similar to those employed in the manufacture of writing paper. An essential requisite in the manufacture of paper is pure water, and paper mills are never found on the banks of sluggish streams or the margin of a marshy, muddy pond. The coloring matter for imparting the various tints to paper is introduced into the beating engine when finishing the "half stuff."

Nevada County Mining Statistics.

There are 45 quartz mills in Nevada county, having an aggregate of 503 stamps, and a crushing capacity of about 750 tons per day. They are divided among the various townships as follows:

Nevada—Deadwood, Murchie, Merrifield, Providences, Wyoming, Nevada City, Pittsburg, Thomas, Martin & Mitchell, Eureka No. 2, Spargo, Kirkham, Crosby, Keith, Stiles, Sneath & Clay, Pennsylvania. Number of stamps in Nevada township, 153.

Grass Valley—Idaho, Scadden Flat, Larimer, Omaha, Bullion, O'Connor, Godfrey (cement), Orleans, Coe, Empire, Alpha, Rocky Bar, Allison Ranch. Number of stamps in Grass Valley township, 180.

Eureka—Parsons, Birchville, California, Great Republic, Rocky Glen, Booth. Number of stamps in Eureka township, 78.

Washington—Patterson, Marker, Yuba, Fall Creek, Diamond Creek. Number of stamps in Washington township, 60.

Rough and Ready—Ironclad, Hudson, Osceola. Number of stamps in Rough and Ready township, 22.

Little York—Sargent & Jacobs (cement), 10 stamps.

The assessed value of mining claims and improvements in the county is \$2,358,640; value of mining ditches, reservoirs, etc., \$1,051,495; total number of mining ditches, 217; number of miles of mining ditches, 524.

HELL'S FIRE ROCK.—Miners are not in the habit of throwing up good contracts for nothing now-a-days; but the Ada mine, in Snake creek, is idle at present, and will be for some time to come, unless some of our rock sharps give a solution to a geological phenomenon which still puzzles the miners of that section. In driving the tunnel, which is now in over 100 ft., a strange formation was encountered. At every stroke of pick the tunnel was filled with luminous vapor, and the weird light made the blood chill in the veins of the superstitious miner. It is needless to say that the contractors dropped their tools and left, and the owners of the property could not induce them to resume their work. They call the rock "hell fire rock," and give the tunnel a wide berth. Some of the rock is being analyzed, and we shall give the result as soon as ascertained. It is probably phosphoretic rock.—*Salt Lake Tribune*.

The Outlook at Bodie.

The present outlook of the mining interests in Bodie, says the *Standard-News*, considering the age of the camp, could not be improved. Within three months the ponderous machinery of the Red Cloud will be in motion and the work of sinking that shaft to a depth of 2,000 ft. prosecuted with all vigor. This will take the water from the Noondays, Oro, Mayhell, Concordia, and permit of their being worked to good advantage, and but a few months will then pass before the full value of the Silver hill mines will be made known, as all that now retards the work being the heavy body of water encountered. The Red Cloud works are this entering wedge for the same character of works that experience has proved must be built on the line of the main Bodie lode before it can possibly be opened up at great depths. Not less than three such works must be erected before Bodie can hope to be placed in that rank of mining camps which the solid merit of her mines entitle her. With proper drainage facilities Bodie will open up to the mining world the richest and most extensive ore bodies ever uncovered. We make this statement purely from the indications shown along the whole length of the line that inevitably point to this conclusive fact. It is true none can positively tell of matters not in sight. Yet, it is equally true that all mining experience proves that stringers, seams of ore and small ledges are but offshoots from large ore bodies, and if followed always lead to them. Twenty years' mining on the Comstock establish this proposition correct, and all the mining experience of the world supports it. We see it exemplified to-day in the Bodie mines, and therefore our conclusions that our mines can be no exception to the rule. It must be remembered that the mines of Bodie are, as yet, almost in virgin soil. Two years since they were all but two or three worked with windlass and whim, the windlass being largely in the majority. Within the past year 25 steam hoisting works have been built and the work of development prosecuted to the water levels. Here it must rest until powerful machinery is set up at such points on the line of the lead as will insure the drainage of the whole line. This can only be done by a combination of the different companies, as the expense is entirely too great for a single company to handle. This proposition every moneyed man understands, and but a short time will pass before it will be acted upon, and the fame of the deep mines of Bodie will extend throughout the mining world, built upon a basis that stock manipulators cannot shake.

Poverty Flat, Idaho.

A correspondent of the *Salt Lake Tribune*, writing from Challis, Idaho, says: Going again up the creek, an ascent and a trail ride of five miles south, brings us to Poverty Flat district, where the Redemption mine is being worked so successfully that during the past month they have taken out 350 tons of good ore, which will well repay for shipping. Near the Redemption we find the Vermont, Broadway, You Know, I Know and others, all being good mines, and being on the same belt as the Ram's Horn, are very similar in quality.

Further up the Salmon river, five miles, comes the district of Killinick, of which Clayton is the town, and location of the Salmon river mining and smelting company, having the following management: Capt. C. B. Rustin, President; Gen. W. W. Lowe, Manager and Treasurer; and W. S. Causland, Superintendent. The works will be in operation within the next three weeks. A wagon road connects Clayton with Crystal, the distance being four miles, and crosses a bridge over the Salmon. By means of this bridge, 180 ft. long, and a road running up the East Fork, a shorter route is obtained for an outlet towards Blackfoot. The districts here described are rapidly coming to the front as ore producers, while the two smelters will, by giving a market for ores, be the means of bringing the mines to that of profitable producers.

FUTURE MINING.—Mining will soon rank among the leading scientific industries of our country. It is only just beginning to be understood. The shadow shafts and short tunnels scattered through the vast mineral region of the great West are as nothing to what the next generation will see. The few great lodes that are worked will yet be surpassed by greater ones. Miners are beginning to learn that in order to find immense lodges, great depth must be attained. At present even but little is known what riches the earth has in store for the future miner. The mode of operations carried on by the miner of early days is now considered child's play, and in years to come the same opinion will be entertained of us. Ten years from now there will be shafts on Bodie bluff and High peak 2,500 ft. in depth, and the machinery will be of the most improved order. The indications now are of such a nature that it is not unreasonable to predict that Bodie will surpass the Comstock in its most glorious days. There are many who believe this and will stay with the camp as long as there is a steam engine at work on the hill.—*Bodie Free Press*.

THERE are now 12 mining districts in Grant county, New Mexico, and there will be double the number at an early day. The prospecting parties which have gone out since Victorio crossed the line, cannot fail to find something. The whole county is seamed with mineral belts.

A Long Island Trout Farm.

We are interested to learn from Eastern papers of the success of a fish-farming enterprise on Long Island, which has been developed by Geo. W. Thompson, who is an old Californian, and during the latter part of his stay in this State was a resident of Brooklyn township in Alameda county. What Mr. Thompson has done at the East may serve as a hint for similar enterprise to some of his old friends who still remain here, for California has many sites well adapted for such work. We shall take from the accounts at hand some interesting paragraphs:

Long Island is noted for its trout farms, and many of them have attained a just celebrity. Most of these trout preserves are situated near the center of the island or at its western end, the only one on the east end being the Noyac trout farm. This farm is owned by Mr. Geo. W. Thompson, who came to Noyac from San Francisco about six years ago. Before Mr. Thompson's purchase of the tract of land now comprising the trout farm it was a perfect wilderness of underbrush and trees. There are now 40 springs upon the place from which the various ponds are supplied, but when the present proprietor entered upon the land a small brook, leading into a pond that supplied the motive power to an old grist mill, was the only water course.

Preparing the Ponds.

The first thing this new proprietor set about doing was to clear the land of underbrush, thin out the trees and convert the brook into a series of ponds suitable for trout propagation. The ponds were dug by hand in such a manner as to give a pleasing variety of outlines, and graded in such a way as to allow the stream an easy fall from one reservoir to the other. There are 30 of these ponds altogether, ranging in size from 15 to 20 ft. in length to an extent of three or four acres. They are separated by wide screens in order to keep the different growths of trout apart. The water takes its course through the most sequestered nooks upon the place, over rocks and pebbly bottoms, and in the shadow of trees and bushes; thus making the preserve as much like the natural haunts of the fish as possible.

In the autumn when the leaves are falling they would soon cover up and sully the water were it not for an ingenious contrivance which Mr. Thompson invented to remedy such a state of affairs. From one pond to the other there is a slight fall of, perhaps, a foot or more, and the flow of the water causes the leaves to cluster about the dividing screens. Where the leaves gather thickest a large wire fly-wheel is placed, turned by the stream itself, which snags in all the light debris and throws it up on the bank on each side. In this way a perfectly clear water course is always insured. To obtain a larger supply of water for hatching, nursery and other purposes, the 40 springs, previously mentioned, were dug, and thus in the driest times of summer there is no fear of dearth of water.

After clearing his land and making the necessary reservoirs for his fish, Mr. Thompson commenced raising trout for market. It requires great familiarity with the habits of trout to be able to tell exactly at what time the female trout is ready to spawn, and it requires equal skill and judgment to treat the fish in such a way that they will experience no ill effects after the spawn is taken from them.

Gathering the Spawn.

When the spawning season arrives the experienced eye can easily detect when the eggs of the female trout have reached maturity. The fish are caught in a light net and put into tubs of clear water. Pans purposely made for the reception of eggs are then placed in readiness, and the female trout are relieved of the spawn in the following manner: The fish is held near the head with the left hand, and the right is clasped around the body just above the abdomen. Then with a gentle downward movement of the right hand the eggs are forced from the trout into the pan. The male trout is then treated in the same manner, contributing a milky fluid, which is dropped into the same pan with the spawn and causes fecundation. The fish, both male and female, are much exhausted after this operation and unless placed where they cannot be molested they are apt to become sickly and die. They are usually put in a separate pond until fully recovered, when they are allowed to mingle with other fish of their own size.

Hatching the Eggs.

The hatching trough is a long narrow box divided into compartments, into which the eggs are placed according to their different stages of maturity. The sides of the trough are charred to prevent the growth of fungi, as any impurity is deadly to the life germ of the eggs. Water from a large reservoir is kept continually running through the hatching trough, and so great is the need of keeping it clear of all impurity or any kind of sediment that before entering the hatching boxes it is forced through seven filters of finest flannel. The time of incubation varies from a few days to much longer terms, according to the character of the season and the various stages of maturity of the eggs.

When the fish are hatched they are minute creatures with a curious little transparent sac attached to the stomach. The sac disappears as the fish increases in size, some theorists attri-

hunting their disappearance to the fact that they furnish sustenance to the young fish, and are gradually absorbed until they are capable of feeding themselves. When the young trout reach this stage they are taken from the hatching trough and placed in what are called nurseries, which are simply a series of large wooden compartments with latticed covers to protect the young trout from their enemies of the air and held. These compartments are separated by wire screens, and through them all flows a shallow stream from the reservoir up the hook. The nurseries are constantly filled with young trout, the various sizes being kept in different compartments. This is a very necessary precaution, for trout are cannibals, and unless great care is taken to keep the larger fish from the smaller the latter would soon be destroyed.

As the trout grow they are removed to larger nurseries, where they are kept until they attain a size of two and a half or three inches, when they are again sorted and placed in the larger ponds.

Sorting and Feeding the Trout.

The process of sorting the trout is, it may be said, of almost continual duration. As soon as a trout outgrows his companions he is caught in a net and placed in more suitable company; for if left among the smaller and weaker fish, he would soon display his cannibalistic propensities. This, of course, applies only to the younger fish, for a three-pound trout would probably find it discouraging work to try and dispatch a two pound brother. Brook trout rarely attain a weight over three pounds, though Mr. Thompson has some beautiful specimens which will weigh nearly four pounds; but they are exceptional cases.

The trout are fed at stated times every day, the food in summer consisting of minnows and other small fish caught in the neighboring coves and bays, and in winter, of beef chopped fine in a machine made for the especial purpose of preparing trout food. The price the trout fetch in the New York markets varies from \$1 to \$1.50 per pound according to the season.

Mining in Colorado.

Mining business during the year 1881 will advance to the front as the favorite industry of the country, and the hulkion product of that year will probably double that of the combined years of 1879 and 1880. Local papers throughout the different mining camps report an increase of population; and of Colorado, Arizona and New Mexico it can be said without exaggeration that more capital will be invested during 1881 than has been within the past five years. Even Leadville makes daily reports of news and rich strikes, which astenish those not already familiar with the formation of that most wonderful camp, without doubt the richest in the world. Silver Cliff is building more mills, and immense ore bins are full, awaiting the completion of the mills. In the meantime, ore running into the thousands of dollars is being taken from mines where heretofore only low-grade ore has been found, thus proving conclusively that with depth silver mines become richer in their precious product. The recent rich finds at Chubb's, on the line of the Denver, South Park & Pacific railroad, has caused the organization of a company to erect reduction works there, while another enterprising company has laid out a town site. The Gunnison country, although much abused by a certain class of interested parties, is without any doubt destined to materially increase Colorado's hulkion product during 1881. The great southwest, which embraces the ever-popular San Juan country, will employ over 20,000 miners next year, extracting the gold and silver from her everlasting true fissures. The other countries, Clear Creek, Boulder and Gilpin, are too widely and favorably known to require any statement regarding their future. Since the discovery of the precious minerals they contain they have contributed a steady income, and their hulkion product will no doubt increase during next year as rapidly as will that of any other district in the State.—*Rocky Mountain Mining Review.*

PROVIDENCE HOISTING WORKS BURNED.—On the 21st inst., at six A. M., the town of Nevada City was startled by a fearful explosion and a dense smoke arising from the vicinity of the several mines on Deer creek, one mile west of town. It was soon learned that the Providence company's hoisting-works were on fire, and that several boxes of Giant powder had exploded, blowing huge timbers and fragments of the burning building in every direction. Fortunately, no one was injured. The origin of the fire is unknown, but it is supposed to have caught in the furnace-room and to have gained such headway before being discovered that the only occupant of the building, the engineer, had no opportunity to remove the powder or suppress the flames. As the fire occurred between the hours when the night shift leave and the day shift go on, there was no one in the mine. The mill buildings of the Providence and the Merrifield works, directly across the creek, were saved only by the energy of the attaches of the several mines in the neighborhood. In addition to their hoisting-works, the Providence lost 800 cords of wood. Their loss of property and the damage resulting from the stoppage of the works and the filling of the mine with water, will fall not far short of \$50,000. There is no insurance. The owners of the Providence property will commence immediately to erect much larger and more extensive works.

USEFUL INFORMATION.

Theory of the Injector.

The explanation of the action of this apparatus, which is generally accepted as the correct one, we give below, substantially as given by Knight. It should be added, however, that there are a number of peculiar features about the action of injectors which are not fully understood, or, at least, upon which engineers are not agreed as to their proper explanation. The general principle of their action is stated, however, as follows: Under a given pressure, the velocity of escaping steam is much greater than that of the water which would be ejected were a hole to be opened in the boiler below the water-line. At a pressure of (say) 90 lbs. to the square inch, the excess of velocity of the steam is about in the proportion of nine to one. As the escaping steam in being condensed, loses none of its velocity, except that due to the friction of the pipes through which it passes, it consequently, after condensation, has a penetrating force about nine times greater than the resisting power of the water in the boiler. At the moment of condensation, it imparts its momentum to the water by which it is condensed, and with which it mingles. For instance, 1,700 cubic inches of steam, on being condensed to one inch of water, imparts sufficient momentum to eight cubic inches of water, by which it is condensed, to exactly balance the pressure of water in the boiler. In this case the opposing forces are in equilibrium; but, combined with any less quantity of water, say seven cubic inches, the momentum will more than suffice to overcome the resistance of the water in the boiler, and the mingled condensed steam and water will force its way into the boiler if a properly-constructed entrance is provided for it.—*Manufacturer and Builder.*

PRESERVING TIMBER IN GROUND.—In speaking of the well-known methods of preserving posts and wood which are partly imbedded in the earth, by charring and coating with tar, it is said these methods are only effective when both are applied. Should the poles only be charred without the subsequent treatment with tar, the charcoal formation on the surface would only act as an absorber of the moisture, and, if anything, only hasten the decay. By applying a coating of tar without previously charring, the tar would only form a casing about the wood, nor would it penetrate to a depth which the absorbing properties of the charcoal surface would insure. Wood that is exposed to the action of water or let into the ground should first be charred, and then, before it has entirely cooled, be treated with tar till the wood is thoroughly impregnated. The acetic acid and oils contained in the tar are evaporated by the heat, and only the resin left behind, which penetrates the pores of the wood and forms an air-tight and waterproof envelope. It is important to impregnate the poles a little above the line of exposure, for here it is that the action of decay affects the wood first, and where the break always occurs when removed from the earth or strained in testing.

GLASS WICKS.—Lamp wicks of spun glass are made in Germany. They are said to supply the petroleum, oil or spirit more regularly, and lamps that are provided with them can be carried about with less danger of going out or scattering sparks and kindling conflagrations. For equal strength of flame the glass wicks give a purer and clearer light; they have a less unpleasant odor; they consume less fuel; in spirit lamps they give a more intense heat, with a more quiet and steady flame.

WHERE THE MONEY GOES.—A French writer states that the Egyptians conceal \$20,000,000 annually of the precious metals; and the Emperor of Morocco has filled 17 large chambers with gold and silver. The solution of the problem of the disappearance of the precious metals from the countries where they are produced, is that the Orient is the reservoir into which continually flows the gold and silver of the Occidental reservoir from which there is no ebb.

CAUSE OF THE LATE ADVANCE IN IRON.—It is said to have been the greed of consumers that led to the heavy importation of iron during the last 10 or 12 months, and not the inability of our manufacturers to supply all the iron the country needed. The *Enquirer* happily remarks: "The United States have at the present more iron than they can possibly use, and facilities for producing at any time more iron than they want—always provided that the consumer does not insist on having supplied to him in one year as much iron and steel as he can use in two years."

ELECTROTYPING WITH IRON.—Herr Bottger describes a process for steeling copper plates by electrolysis. One hundred parts of ferrous-ammonia sulphate, together with 50 parts of sal-ammoniac, are dissolved in 500 parts of pure water, a few drops of sulphuric acid being added to acidulate the solution. The copper plate is connected to the negative pole of a battery of two or three Bunsen elements, an iron plate of equal size being employed as an anode. The solution is maintained at 60° to 80°. The deposit of iron is of a hard, steel-like quality.

WATERPROOF GLUE.—Glue may be made waterproof by adding about one part of bi-chromate of potash, first dissolved in water, to every 30 or 40 parts of glue; but you must keep the mixture in the dark, as light makes it insoluble. When you have glued your substances together, expose the joint to the light, and every part of the glue thus exposed will become insoluble and therefore waterproof. If the substances glued together are translucent like paper is, all will become waterproof; if opaque like wood, only the exposed edges will become so, but they also protect the interior—not exposed parts—against the penetration of moisture.

TO KEEP GRAPES.—Take full bunches, ripe and perfect; seal the end that is out from the vine so that no air can get in, or the juice of the stem run out, and let them stand one day after sealing so as to be sure they are perfectly sealed (if not they will shrivel up); then pack in boxes of dry sawdust and keep in a cool place. They will keep nicely all winter without losing their flavor. In packing do not crowd the bunches; sprinkle the sawdust over the bottom of the box, then sawdust and grapes, alternately, until the box is full.

WOOD CARVING is an industry which is carried to considerable perfection among the Germans, and is fostered by the establishment of carving schools, particularly in districts where the wood used for the work—Spanish walnut, the best walnut the Germans have—is plentiful. There are now 80 such schools in Germany.

TRANSPLANTING EELS.—The French engineering corps has been experimenting for some years past on the transport of young eels by railway, in order to supply various streams in the different departments. Very little care is necessary except to avoid shipment when the temperature descends below the freezing point. They have already successfully transplanted about 1,500,000 eels. The eel would be a useful fish for propagation in California waters.

COMPETENT judges assert that there is no more beautiful wood for ornamental cabinet work than the curled pine of Florida. It is eagerly sought after by European furniture makers, and much of it is shipped from Pensacola. It is said to be difficult to work, and must be handled by the best mechanics with the best tools; but the results obtained amply repay the care and skill expended on it.

SOLDERING LIQUID.—Dissolve scrap zinc in excess in hydrochloric acid by means of heat, neutralize the free acid with water of ammonia, and dilute with an equal bulk of water.

GOOD HEALTH.

Symptoms of Consumption.

Cough is not an early symptom of consumption, necessarily, for there are many cases on record in which cough was not an observed symptom until within two or three weeks of death, and on examination the lungs presented a diseased mass, hurrowed with cavities. Spitting blood is not an early symptom of consumption, necessarily, for about one-third of those who die of that disease do not spit blood at all. Among the very earliest symptoms of forming consumption are combinations of the following, not all, perhaps, observable in any one case: A quicker pulse than common, a paler face, easily chilled after eating, more readily put out of breath than common, less fullness of flesh than usual at the corresponding season of the year, an unusual feeling of unrest on getting up in the morning, a greater tendency to coldness of the hands and feet, every now and then a day passing without any action of the bowels, with a very bad taste in the mouth when first waking up in the morning, a cold is easily taken, is more frequent, and lasts longer and longer, until one cold runs into another, making the confirmed cough, so ominous of approaching ill.

It will be seen at a single glance, from these symptoms, that they all indicate one thing, and that one thing is at the bottom of every case of consumption—a want of vitality; that is, a want of general vigor of system, a constitution.

But of all the things named, it will be more practical to select the two which are seldom if ever absent, in any of the above combinations which result in consumption; hence it is important to be at some pains in stating them in their hearings. A quick pulse and a short breath pervade the disease from its earliest beginnings, during its entire progress, and down to its fatal end. Multitudes of lives might be saved yearly, if these two symptoms were promptly and wisely attended to. The importance of so doing, no language can adequately portray, and if it did, the people would not attend to it, with only here and there an exception. But a great truth is of small seed and of slow growth: yet that growth is certain, and its spread uncontrollable—the more so, as education becomes more general.

The pulse heats about 68 times in every minute of healthful adult life. The range is from 66 to 72. When it is below 66, there is something at fault; when it is over 72, during all the hours of the 24, there is always disease, and if it continues so for weeks and months, there is the strongest ground for apprehension that consumption is approaching. A pulse steadily over

80 beats in a minute, for weeks together, is a forerunner of consumption.

Whatever may be said of auscultation, of sounding, of expectoration, there is in none of these a guide as sure as the condition of the pulse, with the aid of a competent interpreter. It is said that the physicians among some of the Orientals are not allowed to see their female patients, the hand only being put out through the bed curtain, and by feeling the pulse, prescriptive must be made. If the powers of life are being pressed to death, the full, soft, slow pulse tells it in an instant; if active, and actual destruction of organic life is taking place in the body, the inflammatory pulse, quick, wiry, angry, spiteful, at once raises the note of alarm. Every physician knows how gratefully the pulsation, as of woolen yarn beneath his finger, strikes upon his perceptions, on some urgent call, and how troubled if it gives the feeling of a quick vibrating small wire. The multitude of shades of difference between these carry with them their varied impressions, all highly instructive.—*Hall's Journal of Health.*

A Vice that is Sapping Manhood.

If the youth of the present day gave but a thought to the injurious effects of cigarette-smoking, and sturdily tried to avoid the pernicious habit, we are convinced that both their mental and moral well-being would be vastly improved. It has been often stated by good authority that the indulgence of this habit on the part of our youth tends to degenerate the physical stature of the person who is a slave to the cigarette. It may seem a graceful accomplishment to roll the fragile piece of paper with dexterity. There may be an innate desire on the part of an ambitious youth to arrive at that stage in the process of cigarette-smoking when one can swallow the smoke which arises from the tobacco and paper, and let the blue cloudlets find egress through the nose. But we warn our youthful readers that in becoming such adepts in the art which is sapping their manhood, they have entered upon a course which will eventually bring them to an early grave.

Perhaps the injurious effects of this habit would not be so bad where it is not for the vile adulterations which enter into the manufacture of both paper and tobacco. The demand for this form of smoking has been so great, that the market is flooded with imitations made of the worst paper, and the cheapest refuse of the tobacco factory. A physician in New York recently analyzed a cigarette, and found the tobacco was strongly impregnated with opium, while the wrapper, which was warranted to be pure rice-paper, was found to be the ordinary quality of white paper, whitened with arsenic! Thus does the death-dealing abomination stalk through the land, dwarfing the mind and deteriorating the body. A recent writer has said that our next generation will be born of puny-chested, slim-legged, small-necked chaps, and what kind of a generation it will be! Idiots and monkeys! This may seem drawing it rather strong, but we have no doubt that it is not in the main correct. It is truly shameful to see a little fellow not higher than your knee puffing away as if his very life depended upon the effort. It needs the most watchful care upon the part of parents to try and check this tendency to an evil habit in their children. If the consequences of their actions, and the fatal results which an indulgence in cigarette-smoking would have upon their future life were forcibly impressed on them, we think our youth would try to avoid the habit. But if they hid defiance to all parental and friendly council, and continue upon their dangerous course, we can truthfully tell them they may as well give up all chance of ever becoming worthy citizens of this great republic. When manhood is about enfolding its charms to their gaze, it will find them weak, spiritless and unambitious, and they cannot if they would enter upon the race which leads to performance and honor. The vice of their youth has incapacitated them from fulfilling all worthy endeavor. We hope our young readers will give heed to these warnings, and not be so foolish as to pursue a course which will eventually be their ruin. A hint to the wise is sufficient.—*Pacific States Watchman.*

TO CURE FITS OF SNEEZING.—A correspondent of the *British Medical Journal* says: "During the recent rapid change of temperature I caught a severe cold in my head, accompanied by almost incessant sneezing. My unfortunate nose gave me no rest. The slightest impact of cold air, or passing from the outside air into a warm room, equally brought on a fit of sneezing. In vain I snuffed camphor and pulsatilla; the light catarrh still triumphed over me. At length I resolved to see what the maintenance of a uniform temperature would do toward diminishing the irritability of my Schneiderian membrane, and accordingly I plugged my nostrils with cotton wool. The effect was instantaneous: I sneezed no more. Again and again I tested the efficacy of this simple remedy, always with the same result. However near I was to a sneeze, the introduction of the pledgets stopped it at once. Nor was there any inconvenience from their presence, making them sufficiently firm not to tickle, and yet leaving them loose enough to breathe through easily." This is really worth knowing, for incessant sneezing is among the greatest of smaller ills, and it seems only a rational conclusion to hope that this simple plan may furnish the most efficient remedy against one of the most distressing symptoms of hay fever.

The Week.

The week has been characterized by no startling occurrences in the world of mining. The winter will soon be upon us, and many mines at high altitudes will have to close down for the season. With the advance of winter prospecting will to a great extent cease, and the prospectors will have to come back to the camps for a while. The summer campaign has been vigorous and the results are many new mines.

In another column we give the result of the investigation into the Imperial mine disaster. Strange to say, the blame is fixed upon the managers, who are charged with criminal carelessness in using a worthless rope. This is a most serious charge. An old miner once made a suggestion in this connection, which was to have one of the directors go once a day down the shaft. If that was part of his duty he would see that the cages, hoisting gear and all appliances would be all right and of first-class make.

The condition of the mining industry generally all over the United States, wherever mining is done, is excellent. More people are taking up mining as a legitimate investment than ever before. As soon as this principle becomes well understood, and stock transactions paid less attention to, then will the golden era of mining be fairly instituted.

The Presidential party was received with great honors at Portland, Oregon, last Wednesday.

The President's Visit to a Hydraulic Mine.

On Friday, Sept. 24th, the Presidential party, accompanied by Gen. McDowell, U. S. A., and Gen. Bidwell, of Chico, visited the mine of the Spring Valley Hydraulic Gold Company at Cherokee, Cal. They left Chico at 8 A. M., accompanied by a large number of residents in buggies, and, after a ride of 25 miles, reached this mine a little tired and somewhat dusty. Mr. Waldeyer, the Superintendent, met the party at the foot of the mountain and escorted them up the company grade, following the tail flumes and passing the under currents a distance of three miles to the main works.

Here they were received by a brass band, and a salute of pipe-clay blasts to the number of about 200, each explosion hurling into the air fragments of earth, and producing a continuous and prolonged fusillade which was a novelty even to the veteran experience of Gen. Sherman.

The large machine shop of the Company had been transformed into an evergreen bower for the accommodation of the guests, and after the party were sufficiently rested and had partaken of lunch, they were taken into the east opening of the mine where the pipes were playing on the bank. The bank at this place is 400 ft. in height of fine white gravel, and the pipes with a nozzle seven inches in diameter discharge 1,000 inches of water, having a pressure of 312 feet.

President Hayes, under the tutelage of Mr. Waldeyer took charge of one of the pipes, and seemed surprised and charmed with the wonderful disturbance he made among the massive rocks and the ponderous masses of soft gravel he brought thundering down the bank, not to speak of the deluge of spray which he managed from time to time to sprinkle upon his audience. Gen. Sherman tried his hand also, but his appreciation is warped by a professional eye, as he simply remarked: "What a magnificent engine with which to breach a wall."

The party were then taken into the south opening on Table Mountain, and the water turned off to allow them to inspect the flumes and the system of gold saving in hydraulic workings. The flumes are here paved with blocks and are rich in amalgam. Mr. W. explained the process of quicksilvering, etc., and exhibited the rolls of amalgam as they lie in the interstices between the blocks. He then gathered together a ball which he presented to Mrs. Hayes as a sample of quicksilver gold and a souvenir of Cherokee.

They then visited another opening on the lower bedrock, where a large water derrick was working in the blue gravel stratum, and witnessed the process of raising boulders weighing six to eight tons from the pay bottom and depositing them with the greatest ease and rapidity in piles 60 ft. high and 200 ft. away. From here they went to one of the northerly openings, where a bank blast was fired by electricity, the leading wires being carried far out so the party could inspect the process of firing; and when the knob was turned back, with a concussion scarcely greater than the tap of a finger, and they instantly felt the earth quiver beneath their feet and saw the distant earth and rocks rise like the bursting forth of a volcano, the ladies looked appalled and the gentlemen surprised, notwithstanding they were quite prepared for the shock.

The party then repaired to the machine shop where about 200 children, carrying hammers and marshaled by Miss M. A. Walsh, presented to Mrs. Hayes an address of welcome to which she replied. Mrs. Hayes having expressed a desire to witness a sample of the panning process of '49, a workman was sent for a pan of gravel, which was by courtesy taken from one of the richest ground sluices, and after the contents had been washed down to a reasonable weight, Mrs. Hayes was induced to seat herself beside the pool and complete the panning process, which was accomplished in quite a dextrous fashion for so recent an immigrant. The result was several dollars in fine gold and one or two small nuggets. None of our Argonauts in the olden time could have been more pleased with his first-found prospect than Mrs. Hayes when she wiped the mud and water from her hands and exhibited her prospect, shining among the particles among the black sand.

At 3 o'clock the party left for Chico and expressed themselves highly delighted with hydraulic mining. This is the only mine thus far visited by them in California, and they regretted that they were obliged to leave so soon. The day's trip was a most exhausting one, consisting of a wagon ride of about 50 miles of not the best of roads, and four active hours' climbing over the rocks at the mine, but they expressed themselves as fully repaid for all the fatigue and discomfort. Mrs. Hayes noticeably moved around over the rough trails with the greatest ease and rapidity, and she showed more endurance and appreciation than any woman who has ever visited the mine.

On their way down the mountain the attention of the President was called to the deposit of tailings extending into the Sacramento Valley, and the conflict between the miner and farmer visibly presented, as well as reference to the eventual harm to the rivers, and a claim made for Congressional aid in behalf of all parties interested, as all hold titles from the same source.

Limestone not a Mineral.

The Commissioner of the General Land Office has rendered a decision in the case of Elias Jacobs, which is one of importance to miners. It seems that Jacobs made application to enter, under the laws providing for the sale of mineral lands, a certain tract in Tulare county, in this State. He proved that the limestone was of good quality, and the land more valuable for its limestone than for agricultural purposes. His claim was for 1,500 by 600 ft., and was duly recorded and application for patent made. James Newton filed an adverse claim, basing his allegation of ownership on his pre-emption claim involved in the case of said Newton vs. the S. P. R. R. A protest, dated Aug. 1, 1879, was filed by the attorney for the S. P. R. R. Co., setting forth that limestones is not usually classed mineral, and that at the time of the grant to said railroad company only the precious metals were dealt with by the Government as minerals in its disposition of land, and was not intended to be excepted from the grant to said company.

The Commissioner was not aware of any application ever having been made under this act of 1866 for a patent on a limestone ledge; but when the land was agricultural, the existence of limestone constituted no objection to its entry as such.

The Commissioner is of the opinion that the act making the grant to the railroad, did not except as mineral such as were simply valuable from deposits of limestone, for such lands under the laws then in force were not subject to disposal as mineral. He says further: "I find in the statute books an act of Congress providing a specific mode for the acquisition of title to lands valuable chiefly for stone. This act, which was approved June 3, 1878, provides that lands of such character in the State of California shall be sold to qualified applicants at the rate of \$2.50 per acre."

"I entertain grave doubts that limestone should be classed as a mineral, or disposed of as mineral land under any of the laws of the United States. If such lands are to be classed as mineral, they must necessarily be reserved from disposal under the laws providing for settlement rights, and in that manner parties who are now occupying lands for agricultural purposes, and who have, perhaps, made extensive improvements, would be prevented from acquiring title under the pre-emption, homestead or other agricultural land laws."

"The act of June, 1878, may be considered a Congressional interpretation of the mining laws then in force, to the extent of holding that they did not provide a mode for the disposal of land valuable chiefly for stone. But in carrying out the idea of classification, the moment land valuable for certain character of stone is decided to contain 'valuable mineral deposits,' it is no longer, unless the mineral is useless on account of the expense and labor in procuring it, subject to entry under the various agricultural land laws, and is excluded from all grants of land which make an exception of mineral lands."

"In my opinion lands valuable for limestone do not necessarily fall within the classification of lands as mineral under the opinion of the honorable Attorney-General."

"And in view of the fact that since said opinion was rendered, Congress has by legislation provided a special mode for the sale of such lands, I am not inclined to treat them as mineral."

"In treating of the classification of land into mineral and agricultural, I am not strictly confined to the geological terms and definitions. Lands which are principally valuable for agricultural pursuits, may contain mineral deposits, as the term mineral is scientifically applied. Under the United States mining laws the deposit should be a valuable mineral; and in the administration of the law, I am often called upon to decide in a case between agricultural claimants and mineral affiants whether the land is more valuable for agricultural than for mineral purposes."

From this decision it will be seen that lands in California containing limestone and useless for agricultural purposes, can be purchased only under the timber and stone act of June 3, 1875.

WHAT came very near being a very disastrous accident occurred on Sunday night on Oakland wharf, and as it was one man was killed and another badly hurt. The engine and tender of a train ran off an open switch and pitched through the bridge into the water alongside the embankment. The engineer, W. C. Brown, was drowned. Though violently shaken up, the occupants of the cars, with one exception, were not injured. An inquest was held on Brown's body, and the death verdict was accidental drowning.

NORDENSKJOLD has just left Berlin, expressing deep gratitude for the cordiality shown to him there. He dined with the Emperor and Empress on the day before his departure. The Professor will start northward upon his new Arctic expedition in 1882, from the month of the Lena. A new vessel is now being built for him in Norway, and Herr Silurikoff, a wealthy Russian, has offered to defray all the expenses of the expedition.

"Criminal Neglect of the Management."

At the conclusion of the coroner's inquest into the Imperial mine disaster of last week, the jurors of both Gold Hill and Virginia find that the "cable was defective by criminal neglect of the management of said Imperial mine." Here, for once at least, the blame is fixed upon some one. The testimony elicited at the inquest was very voluminous and interesting. The testimony of several witnesses condemned the cable, as it was shown to have been rusty, rotten and full of broken wires.

Louis Beckman, formerly ropeman at the Imperial mine, had examined the rope which broke in the Imperial shaft; saw a coil of it about 1,000 ft. long; examined it in company with Mr. Lewis; found the whole cable, almost from end to end, uncovered and rotten; it was not covered with tar, but with rust; to keep a cable from being eaten, it must be covered with tar; some of the wires were broken, the ends of the broken strands sticking out; the cable was unfit for use in any mine; the effect upon a cable falling down a shaft would be to smash it up; there was no tar on the cable from one end to the other; know it was the same cable by the peculiar make of it.

Harry Kyander, also a ropeman, testified that the rope did not look as if it had been well cared for; the rope was bad all through; would not have considered it prudent or safe to hoist or lower men or material with such a rope; if at work tarring the rope I could tell at a glance that it was defective; it was badly worn, strands were rotten through, and the tar had been washed off by the water in the shaft.

Richard Lewis had been mining two years; before that time worked on wire ropes in England one year; afterward was seven years at sea; had to look after wire ropes all the time; had examined the Imperial rope in company with Mr. Beckman; examined it thoroughly; it was defective from end to end; the wires were eaten and corroded, and the cable was covered with nothing but rust; considered it a highly unsafe cable to use in any mine; work at the Union shaft; every 30 or 40 days the cables there are changed.

H. H. Coote who has been ropeman at the Hale & Norcross for seven and a half years examined the rope, the better end of it very particularly; it was in a very bad condition, there were so many broken ends sticking out of the rope that it looked like a porcupine's back; these had been broken so long that many of them were worn thin as the point of a needle; the ends sticking out were from one to three inches long; considered the condition of the rope due to gross neglect of the superintendent and foreman; it should have been taken out of the shaft three months ago; the rope was worn out because it had been used and neglected too long; there was no tar on the rope, but the stuff that had been tar had turned to rust; in the case of a double or triple decker cage there should be a safety to each deck; when a rope breaks on the sheave the rope jumps off and bounds to the sheet iron flooring at the mouth of the shaft; if the safeties are in good condition they cannot fail to act; the Hale & Norcross ropes are examined every morning and tarred fresh every week; the Imperial water is very hard on ropes, but the Savage and Hale & Norcross water is as bad as any on the lode. The testimony of others was to the same effect, and although there was some counter testimony the jury found a verdict as above.

A WOMELSDORF, Berks Co., Pa., correspondent of the Reading (Pa.) Eagle, says that Mr. Samuel J. Tilden has offered \$1,500 for "the largest dog in America," which is now at that place. The dog is an Ulndog, and was bought in Germany last summer. He weighs 182 pounds, measures 6 ft. 9 inches from tip of nose to tip of tail, and is only 2 years old. He attracted Mr. Tilden's attention at a recent dog show.

PROF. ALEXANDER GRAHAM BELL, the inventor of the telephone, is described as a handsome and courtly man, still young, and the possessor of very black eyes. He is a Scotchman and was educated in Edinburgh. The Volta prize, just awarded to him as having made the best electrical discovery of the past 15 years, brings him the pleasant sum of \$10,000.

A WONDERFUL strike of free gold was made in the Ford & Mullen mine recently. Walter Ford, one of the owners, has become demented over his good fortune. His friends hope his madness will only be temporary.

THE Butte Miner (Mon.) says: 1,000,000 lbs. of mining and milling machinery and salt, belonging to the Alice company, are stored at the Utah and Northern terminus awaiting transportation.

THE Seattle Coal Company is making arrangements to increase the product of the mine from 600 to a 1,000 tons of coal per day.

PHENIX, Arizona, has three Sunday schools, six secret orders, a literary society and a library association—all flourishing.

THE mining prospects of New Mexico were never so good as now.

New Highways to Europe.

We have of late referred to matters pertaining to our outlet for produce to the European markets. As the production of our State, and of the Pacific coast generally, is now being largely increased and diversified, the subject of transportation routes becomes more and more important. The present facts that charters for grain to Liverpool are inordinately high and grain wretchedly cheap, are enough to awaken interest in any movement which promise in the future to multiply our outlets, and consequently increase the chance of shipping produce at a reasonable rate.

The advance of the Southern Pacific railway eastward through Arizona, the speedy connection with roads coming westward, and the promised off-shoot from the main line to New Orleans or Galveston, or some other point on the Gulf of Mexico, are all matters of general interest. The idea held by some that the new approach to the gulf will facilitate the shipment of California grain to England, by rail to the gulf and by ship across the Atlantic, offers a route in competition with ocean vessels around the Horn, which is certainly worthy of contemplation. It seems quite possible that a regular line of steamers from this gulf port to England would find abundant traffic in grain eastward and immigrants and merchandise westward to return a good profit to the ship owners. The new railways through the lower latitudes of the country will open up a vast domain to settlement and lead to the development of many mining and agricultural enterprises. If grain can be hauled and transported from this State to the gulf with anything like the facilities and cheapness with which it is taken from the new grain fields of the Northwest to the Atlantic ports, it will surely be a great factor in deciding how to get our massive grain crops to the consumers with much less outlay for transportation.

The map which we give on this page will be useful to students of our situation, with reference to our foreign markets. From the slightest comparison of distances it appears how expensive in point of distance and time is the present route around the continent of South America. Although the line is not drawn on the map, the reader can easily trace it from our grain fields to the Gulf of Mexico, and thence across the Atlantic. It will be seen that there is but a comparatively slight deviation from a straight line in the proposed route. If those who will have the management of the new line will but employ a generous and wise policy, they can make their highway of inestimable advantage in developing the country through which their line runs, and in enhancing the prosperity of the terminal State of California. The possible effect of the new route to the Gulf of Mexico was made the subject of remark by Hon. H. M. La Rue, President of the State Agricultural Society, in his annual address delivered last week at Sacramento. He said:

When the great wheat-growing valleys of California are connected with New Orleans by rail over the level grades of the southern route, the commercial lines to the final market for our wheat will be shortened by 10,000 miles. We will then have a constantly moving means of transportation at what I have reason to hope and believe will be reduced rates. The average inland tonnage on our grain now is about \$3.50 per ton. The average ocean tonnage to Liverpool is about \$13 per ton, aggregating \$16.50 per ton from the station or landing to the ultimate market. By the Southern Pacific railroad the pro rata of ocean to rail transportation will be reversed. The tonnage rate from New Orleans to Liverpool will not exceed \$5 per ton. Thus leaving \$11.50 per ton as the pro rata to rail transportation, and without increasing the aggregate rate. If expectation in this direction is well founded, the wheat product of California will possess higher advantages in the market than hitherto enjoyed. The completion of this southern route will introduce the now wanting element of competition with the long voyage around Cape Horn. It will also enable the shipper to receive quicker returns. Its further advantages will be found in the opening of markets for the orchard and dairy products of southern California, and it is within the range of possibilities to ship green fruit and fresh beef to the English market by that route. At this time fresh beef is shipped from points on the Missouri and Mississippi rivers by way of New Orleans to England, and the time from Sacramento by rail to the Crescent City is shorter than the time from Kansas City to the same point by water.

We also introduce this map to bring to the notice of those who have not already consulted their atlases, how notable a cut-off is the Isthmus canal, which is now being urged and is awakening much popular interest in this State. A glance at the geography of the enterprise, as shown upon this map, will do more to display its advantages than a host of statistics, although these are of great value in enforcing the importance of the object lesson in the map. The canal does not offer so speedy a relief as the proposed gulf route, but it should, nevertheless, be regarded as a positive need of our industrial growth, and must be in part the measure of the same. This view is being earnestly advocated by those who are best informed of our present and future productive capacity. A committee of the San Francisco Board of Trade has given the canal and its possibilities prolonged and diligent study. They issued a supplementary report last week, mainly to meet the errors of Eastern writers, who claim that the business of the canal would be small, etc. They give the following figures of the wheat trade of this State and Oregon this year:

A fair estimate of the wheat surplus of this State this year places it at 900,000 tons, which alone would require, allowing passage both ways, an aggregate shipping tonnage of 1,800,000 tons. An examination of the San Francisco Custom House statistics for 1879 shows that during that year there arrived from Australian ports vessels aggregating 125,450 tons. With this exception, our wheat tonnage would all have used a canal both ways, making 1,674,544 tons, an excess of nearly 50,000 tons over the

estimate given, on our wheat alone. Oregon has a surplus of about 200,000 tons of wheat this year, which, on the same basis as the California requirements are estimated, would add 375,000 tons more, making a total of above 2,000,000 tons for the export trade of California and Oregon alone. Our producers stand to-day face to face with this great fact. Oregon and California have only one fifth the necessary tonnage available for this purpose. This deficiency involves loss of time and expense; both ruinous to the producer. Were the Inter-Oceanic canal open, we could more easily obtain tonnage, and at the same time save, on a moderate estimate, some \$8,000,000 on this year's wheat crop alone.

And who will undertake to fix the limit of our production? The President of the California State Agricultural Society, in his annual address (Sept. 21, 1880), "estimates from reliable data this year's wheat crop at 1,600,000 tons." He deplored "the disadvantage of California farmers, in that their wheat has to go to Europe via Cape

isolated position, and rely upon long and expensive means of transportation. The world is the market for our diverse and rich productions, and barriers of distance and time must be swept away. The future of our favored territory is a grand subject for contemplation, but it should be cherished with no idle rapture. Every stirring thought should be father to an act, until the longed for results shall be realized.

KLEPTOMANIACS.—The London *World* made the startling discovery that kleptomania was common in fashionable society, and that thefts of jewelry, furs and wraps were frequent in the

GEOGRAPHICAL POSITION OF CALIFORNIA IN THE COMMERCE OF THE WORLD.

Horn, arriving there after the Atlantic and Black Sea ports have supplied the immediate demand," and declared the great problem of the future to be "transportation and market." He further states "that with the cultivation of available lands now unused, the possibility of the wheat production of California in the near future, are 3,000,000 tons per annum." If this be true of California, what may we expect from the development of Oregon and Washington Territory? With this light before us, how futile the idea that an inter-oceanic canal will lack tonnage to secure pecuniary success? Let us consider our rapidly-increasing wine, wool and other interests. Freed from the fetters of expensive transportation, our whole coast would feel new life.

We place all these facts prominently before our readers that their bearing upon our future may be discussed by all, and a general influence be exerted toward the promotion of enterprises which are of such signal importance. We cannot longer afford to occupy a comparatively

hall rooms and cloak rooms of the West End. Instances were given, names and places being suppressed. Truth followed in the same strain, and told how a light-fingered lady of title stole a sable cloak from a ducal mansion; also, how another lady of title lost a diamond necklace. It was said these conveyances of property could not have been inadvertent, seeing that expensive overcoats, costly lace shawls and other property were invariably replaced by shabby articles. In several cases the thieves were caught in the act, but, protesting error, were permitted to go, on restoring the plunder.

The Yellow Jacket pumps are running regularly and well, and are raising about 600,000 gallons of water per day.

Recovery of Sulphur in Silver Leaching.

From Aaron's Lixivation of Gold and Silver.

The quantity of sulphur required to precipitate silver is really only as 16 to 103, but great waste occurs in the usual practice from two causes. Firstly, there is always a certain quantity of base metal dissolved with the silver, which also takes its portion of sulphur from the calcium sulphide; and secondly, a large proportion of the sulphur is thrown down in a free state, which, in the usual course of proceeding, is totally wasted by being burned off in roasting the precipitate.

The reason of this precipitation of free sulphur is, that the precipitant is necessarily a pentasulphide, for the calcium monosulphide is insoluble, and the bisulphide is only soluble with heat (vide Regnault), so that we are reduced to the pentasulphide for useful effect. But in the precipitation of silver, we can only combine one atom of sulphur with one of silver, and as the atom of calcium in the pentasulphide takes the substance with which the atom of silver was combined, there remain four atoms of sulphur unoccupied and useless. Base metals act similarly, only arsenic and antimony being able to form sulphides containing five atoms of sulphur.

There are two ways to recover the free sulphur from the precipitate. The first consists in subjecting the mass to heat in a retort, and condensing the sublimed sulphur. The second method, original with myself, and which I much prefer, is to boil the unwashed precipitate in a vat, by a jet of steam, with water, and slaked lime carefully added. The free sulphur combines with the lime, producing at once the precipitating solution of calcium polysulphide, and much more quickly than the flowers of sulphur. Three-fourths or more of the sulphur is thus recovered for re-use. It is a question of cost whether it will pay to do it or not. In San Francisco sulphur is so cheap that there is not much economy when the trouble is considered, but in some places it would pay.

Mill Building.

There seems just now to be a mania for building quartz mills. We hear from all over the country of new mills, mostly for new mines. While it is pleasant to note so much apparent prosperity in the mining business, it is safe to think also that a good many more mills will be built than are really needed. It is often a most convenient way to "hoist" a stock—to order a mill.

In looking over our exchanges this week we were struck by the great number of mills in process of construction. In many instances they are nearly completed. In a great many more instances, the ore production is delayed till reduction works are finished. It is by no means the case, however, because a mining company builds a mill that its ore production will increase, or that it will ever have any more ore. A mill will often sell a mine when ore will not. It is not safe, therefore, to judge of the prosperity of a mine by the fact that a mill is being built.

COLORADO, NEW MEXICO AND ARIZONA.—We have received from A. L. Baercoft & Co., Rand, McNally & Co's. "Illustrated Guide to Colorado, New Mexico and Arizona," a work which also contains the general mining laws of the United States, Colorado, New Mexico and Arizona. There is also a map, showing every town, and routes to the different localities. This guide contains a description of country, soil, climate, timber, agricultural and mineral lands.

ROBERTSON PROCESS.—A New York telegram says: "Hale, the piano manufacturer, has, with his friends, bought a controlling interest in the Robertson Electric Ore Reduction Co. The new deal puts the process in the hands of a 'strong company' of capitalists." If this "strong company" can make a success of the process in any other way than by selling stock they will do more than was done in this State. It has been pretty thoroughly tried out here but with unsatisfactory results.

In the Sutor tunnel good progress is made now in both headers. Ventilation at the south header is good, but along the south lateral the heat is in some places excessive. A new plan for remedying this will now be tried. Buxes are going in to take air from the north branch to the south branch. The distance is great, but the chances for success are good. The work of carrying forward the drain of the main tunnel progresses well.

The New Yorkers have been bored so much with importunities to buy mining property, that not long ago, as the story runs, a notice was stuck up in the office of a leading hotel, bearing this inscription: "No mines taken in payment for board."

It is stated that a cracked church bell at Carson has been successfully repaired at the railroad shops by running melted metal into the crack of the bell, first placing it in an earth mold. Bell founders have held this feat to be impossible.

Making and Preserving Cider.

As the cider season is at hand, the following suggestions taken from an article in the *Scientific American* may be of use to some readers: A pure, sweet cider is only obtainable from clean, sound fruit, and the fruit should therefore be carefully examined and wiped before grinding.

In the press, use hair cloth or gunny in place of straw. As the cider runs from the press let it pass through a hair sieve into a large open vessel that will hold as much juice as can be expressed in one day. In one day, or sometimes less, the pomace will rise to the top, and in a short time grow very thick. When little white bubbles break through it, draw off the liquid through a very small spigot placed about three inches from the bottom, so that the lees may be left behind. The cider must be drawn off into very clean, sweet casks, preferably fresh liquor casks, and closely watched. The moment the white bubbles, before mentioned, are perceived rising at the bung-hole, rack it again. It is usually necessary to repeat this three times. Then fill up the cask with cider in every respect like that originally contained in it, add a tumbler of warm sweet-oil, and bung up tight. For very fine cider it is customary to add at this stage of the process about half a pound of glucose (starch sugar) or a smaller portion of white sugar. The cask should then be allowed to remain in a cool place until the cider has acquired the desired flavor.

In the meantime clean barrels for its reception should be prepared, as follows: Some clean strips of rags are dipped in melted sulphur, lighted and burned in the bung-hole, and the bung laid loosely on the end of the rag, so as to retain the sulphur vapor within the barrel. Then tie up half a pound of mustard seed in a coarse muslin bag, and put it in the barrel, fill the barrel with cider, and add about a quarter of a pound of isinglass or fine gelatine dissolved in hot water. This is the old-fashioned way, and will keep cider in the same condition as when it went into the barrel, if kept in a cool place, for a year.

Professional cider makers are now using calcium sulphite (sulphite of lime), instead of mustard and sulphur vapor. It is much more convenient and effectual. To use it, it is simply requisite to add one-eighth to one-quarter of an ounce of the sulphite to each gallon of cider in the cask, first mixing the powder in about a quart of the cider, then pouring it back into the cask and giving the latter a thorough shaking or rolling. After standing bunged several days to allow the sulphite to exert its full action it can be bottled off. The sulphite of lime (which should not be mistaken for the sulphate of lime) is a commercial article, costing about 40 cents a pound by the barrel. It will preserve the sweetness of the cider perfectly, but unless care is taken not to add too much of it, it will impart a slight sulphurous taste to the cider. The bottles and corks used should be perfectly clean, and the corks wired down.

A little cinnamon, wintergreen, or sassafras, etc., is often added to sweet cider in the bottle, together with a dram or so of bicarbonate of soda at the moment of driving the stopper. This helps to neutralize free acids, and renders the liquid effervescent when unstopped; but if used in excess, it may prejudicially affect the taste.

Extensive Iron Mine.

About three miles from Clipper Gap and six from Auburn in Placer county, are located the smelting works and mines of the California Iron Co. The mines were located about 10 years ago by Judge Meyers, G. W. Applegate and others, and sold a little over a year ago to Messrs. Irving M. Scott (of the Union Iron Works), A. P. Hoatsling, wholesale liquor dealer, and Egbert Jndson, Powder Co., all of San Francisco, who compose the California Iron Co. It is not a corporation. The company has bought 13,000 acres mostly on account of the timber. Extensive and substantial works are being erected, and will be completed about October 1st. The capacity will be 10,000 tons per annum. One hundred men are employed at the works and about 100 at the charcoal kilns and in the woods. Four thousand bushels of charcoal will be consumed each day.

Quite a town has already sprung up adjacent to the works. No name has as yet been given it, but it is built with a street 100 ft. wide and the houses are in regular line. When all is ready for smelting the company will have expended \$100,000. The ore is mostly of the magnetic kind and is almost free from sulphur and other foreign metals. It works 70% and makes superior iron.

The company expect to get a contract for casting the gas mains for the new San Francisco gas company. If this experiment proves a success there will be additional furnaces erected and a rolling mill is a thing spoken of in the future. All the machinery and furnaces are of the latest improvements and everything is substantially built. The various departments are under the supervision of able mechanics who have had much experience in Eastern iron works. A tramway is being built from the works to Clipper Gap station. The whole is under the charge of Mr. P. Fitzhugh.

Business Directory.

WM. BARTLING.

HENRY KIMBALL.

BARTLING & KIMBALL, BOOKBINDERS,

Paper Rulers & Blank Book Manufacturers.
505 Clay Street, (southwest corner Sansome),
SAN FRANCISCO.

JOHN A. CHURCH, E. M. PH. D. MINING ENGINEER,

Room 75, 115 Broadway, New York.

Agent for PADDOCK'S Ore Dressing Machinery.
Mining Machinery supplied.

San Francisco Cordage Factory.

Established 1856.

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.

Extra sizes and lengths made to order on short notice.
TUBBS & CO.,
611 and 613 Front Street, San Francisco

Pumping Engine For Sale.

NEW UPRIGHT WILCOX ENGINE.

16-inch Cylinder, 6-inch Stroke. About 8-Horse Power. Will raise 3,000 gallons per hour. Was used to dig the well at Chronicle office. Never used otherwise, and is in perfect order.

PRICE, \$300.

Mr. Wilcox sold similar engines at \$300 each. I have taken this engine as an attorney fee, and will sell it for this price and WARRANT it. Address

MANUEL EYRE.

Law Office, No. 636 Clay St., room 25, S. F.

John Olsson, Model Maker.

Models for the Patent Office, in Wood or Metal. Separate rooms for inventors to perfect their inventions. Chemical Apparatus. Pressing and Stamping of all kinds of Metals.
55 FIRST ST., OPP. UNION FOUNDRY.

GOLD SAVING SILVER PLATED

Amalgamating Plates,

FOR QUARTZ MILLS AND GRAVEL CLAIMS.

ALSO, CHALLENGE SWINGING PLATES,

For use in Sluices for Saving FLOAT GOLD. Constantly on hand Plate of all Sizes; are prepared to fill orders on short notice. Old Copper Plates Purchased. Replated or Gold extracted by our process, whereby we save the Copper and remove the Gold at a very small expense.

ists, Mining Companies, Milling Companies, Prospectors,
etc., to our stock of Clay Crucibles, Muffles, Dry Cups,
etc., manufactured by the Patent Plumbago Crucible
Co., of London, England, for which we have been
made Sole Agents for the Pacific Coast. Circulars
with prices will be sent upon application.
Also, to our large and well adapted stock of**Assayers' Materials & Chemical Apparatus,**Having been engaged in furnishing these supplies since
the first discovery of mines on the Pacific Coast.
Our Gold and Silver Tables, showing the value per
ounce Troy at different degrees of fineness, and valuable
tables for computation of assays in grains and grammes,
will be sent free upon application.

JOHN TAYLOR & CO.

W. BRUCKNER'S**ROASTING FURNACE**

AND

Ore Pulverizers.

(Awarded the Premium Gold Medal at Naples, Italy.)

The furnace is especially adapted for roasting rebellious
ores; there are more than fifty in use in Colorado, giving
perfect satisfaction.The Ore Pulverizer is built in different sizes. It is prefera-
ble to Stamp Mills because it requires less power and less
repairs than Stamps. No extra expense for setting up, and
no foundation. Less weight and less cost than stamps.
Furnished also in sections for packing.

For circulars and prices apply to

Concentration of Ores (of all kinds), including
the Chlorination Process for Gold-bearing Sulphurets,
Arsenurets, and Gold and Silver Ores generally, with
120 Lithographic Diagrams. 1887.This work is unequalled by any other published, embrac-
ing the subjects treated. Its authority is highly esteemed
and regarded by its readers as containing, as it does, much
essential information to the Miner, Metallurgist,
and other professional workers in ores and minerals, which
cannot be found elsewhere in print. It also abounds
throughout with facts and instructions rendered valuable
by being clearly rendered together and in simple or-
der. It contains 120 diagrams, illustrating machinery
etc., which alone are of the greatest value. PRICE, \$7.50ROASTING OF GOLD AND SILVER ORES (Second Edition)
and the Extraction of their Respective Metals without
Quicksilver. 1885.This rare book on the treatment of gold and silver ores
without quicksilver, is liberally illustrated and crammed full
of facts. It gives short and concise descriptions of various
processes and apparatus employed in this country and in
Europe, and explains the why and wherefore.It contains 155 pages, embracing illustrations of furnaces,
implements and working apparatus.
It is a work of great merit, by an author whose reputation is
unsurpassed in his specialty.

Price, \$3.00 cloth, postage free.

Books for Miners and Millmen.KUSTEL'S CONCENTRATION OF ORES (of all kinds), includ-
ing the Chlorination Process for gold-bearing sulphurets,
arsenurets, and gold and silver ores generally, with 120 litho-
graphic diagrams. 1887. This work is unequalled by any
other published embracing the subjects treated. Post-paid,
\$7.50. Printed and sold by Dewey & Co., S. F.AARON'S TREATISE ON WORKING SILVER ORES.—Illustrated,
114 pages. 1875. A useful and practical work, free
from technicalities and extremely serviceable for miners' use.
Post-paid, \$2. Published and sold by Dewey & Co., S. F.COFF'S HANDBOOK OF MINING LAWS.—Containing the
U. S. Mining Laws, Digest of Decisions, Forms, etc., 1877.
Pocket size, and very handy and convenient for miners.
Post-paid, \$1.00. Sold by Dewey & Co., S. F.

PACIFIC POWER CO.Room with steam power to let in the
Pacific Power Co.'s new brick building,
Stevenson street, near Market. Eleva-
tor in building. Apply at the Com-
pany's office, 314 California street.Cups for Engine, Machine and Shaft Bearings and Loose
Pulleys. We furnish the Albany Cylinder Oil (a solid), \$1
worth of which will last as long as from \$2 to \$10 worth
of Oil, with no stop, and with one-twentieth the ATTEN-
TION required by the best Oil Cups.If the Cups are not satisfactory, we will receive them
back and make no charge.Cylinder corrosion is
not so much owing to
impure tallow or oil as
to the fact that those
animal fats do not main-
tain their integrity
under steam heat, but
decompose and set free
acids which attack and
destroy metal.The Albany Cylinder
Oil does not contain
fatty acids—is incor-
porated being decomposed
and does not form in-
soluble soaps.If it becomes mixed
with boiler incrustation
it diminishes its tenden-
cy to cling to the sides
of the boiler, and thus
exerts in this respect also
also a beneficial action.**THE ALBANY
Cylinder Oil**Is now in use through-
out the world, and we
refer to nearly all first-
class establishments on
this coast for evidence
of its efficacy.**Pure Winter Strained Lard Oil**

By every vessel from New York.

ALBANY SPINDLE OIL,**Genuine West Virginia Lubricating Oil,**

SIGNAL OIL for outside lights of vessels, etc.

NOW READY!

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW ON SAWS!History, Development and Action; Classification and Com-
parison; Manufacture, Care and Use of SAWS of all
kinds. Quarto. 234 Illustrations.

By ROBERT GRIMSHAW, Ph. D., M. E.,

Member of the Jury on Wood-working Machinery at Paris
Exposition of 1878.This thorough work, impartially written in a clear, simple
and practical style, treats the saw technically, analyzing
its action and work, and describing, under the leading classes
of Reciprocating and Continuous Acting Saws, the various
kinds of large and small hand, ash, Mulay, jig, drag, circular,
cylinder and hand saws, as now and formerly used for
crosscutting, ripping, scrollcutting, and all other sawing
operations in wood, stone and metal, ice, ivory, etc., in this
country and abroad. With appendices concerning the details
of manufacture, setting, sawing, running, filing, etc., tables
of gauges, log measurements from 10 to 24 feet, and from 12
to 48 inches, lists of all U. S. Patents on Saws from 1790 to
1880, and other valuable information. Elegantly printed on
extra heavy paper, wide margin, copiously indexed.
Owing to an increase of nearly 100% in number of pages and
illustrations since first projected, the price is this date made
\$2.50, postage paid.

ing, Electrotyping and Stereotyp-
ing done at the office of the MINING
AND SCIENTIFIC PRESS, San Francisco, at favorable rates.

News in Brief.

THE epizootic has reached New York city. The crop prospects in India are improving. The Chileans again bombarded Callao August 31st.

GREAT damage is being done by floods in Texas.

HEAVY rains prevail in various portions of England.

THERE are several mild cases of varioloid at Stockton.

THE public debt was reduced \$12,000,000 in September.

SEVERAL turfmen are willing to give \$100,000 for Maud S.

EIGHT bodies have been recovered from the Hudson-river tunnel.

SOME of the Marquesans have revolted against the French authorities.

VENAGO, a large village in Switzerland, has been nearly destroyed by fire.

BELFAST is to be the next meeting place of the United Presbyterian Council.

MONSTER land meetings in Ireland. Parnell denounced the Liberal Government.

STRIKING workmen in Jagero, Russian Poland, have committed grave excesses.

ALL the fears in regard to the failure of crops are dispelled in most parts of India.

THE recent heavy forest fires which raged near Portland, Or., did great damage.

GALES and floods have caused great damage to the unharvested crops in Hamburg.

AN attempt to blow up the Czar's yacht Livadia at Glasgow has been frustrated.

THE Chinese in Peru are putting themselves under the protection of the British flag.

THE London and S. F. Bank has reduced its capital stock from \$600,000 to \$420,000.

A STEAMER which left Hamburg for New York Saturday brings \$1,000,000 in gold.

THE Oregon stage was robbed near the summit of Siskiyou mountain Thursday night.

THE Turkish Sultan and the Albanian chiefs reiterate their refusal to surrender Dulcigno.

THE miners at Corning, O., have compelled the saloon keepers to close their places of business.

ABOUT 400 Chinese and white men have begun work on the railroad grade near Spokane, W. T.

THE track of the Southern Pacific railroad has reached the New Mexico line—140 miles east of Tucson.

JOHN ADAMS shot and killed Isaac Wilson Sunday night, Sept. 26th, in Knox township, Napa county.

A POWERFUL party in Norway are agitating separation from Sweden, and the establishment of a republic.

THE Cuban insurgent chief, Carrillo, with his remaining followers, have surrendered to the Spanish authorities.

THE revenue of the Government the past year amounted to \$334,000,000—over \$1,000,000 for each working day.

A NAVAL review on a more liberal scale than that of last year will take place in Hampton roads about October 15th.

DURING the ten years ended June 30, 1880, immigrants to the number of 2,812,177 arrived at ports of the United States.

LORD MOUNTMORRIS, a landowner on had terms with his tenants, has been found murdered near Ballinacree, Ireland.

THE fastest time ever made by a pacer on a half-mile track was accomplished at Omaha this week by Mattie Hunter—2:16.

THE Circuit Court of Oregon has decided against the law prohibiting the employment of Chinese on the streets of Portland.

THE Burmese tyrant has arrested his mother and sister, with thirty other persons. It is rumored that executions have recommenced.

U. S. GRANT, Commander-in-Chief, has called a convention of the Union veteran soldiers and sailors, to meet at Indianapolis, October 7th.

THE Supreme Court has decided that there is to be no Municipal election in San Francisco this year, the present officials holding over.

JAMES G. FAIR, a member of the well-known "Bonanza firm," has announced his willingness to be a candidate for United States Senator from Nevada.

THREE women were poisoned at Wilkesbarre, Pa., not long ago by using cornmeal in which arsenic had been placed for the purpose of destroying rats.

PAYMASTER NELSON, of the United States Army, has been arrested and taken to New York for Kansas City for trial by court-martial on charge of embezzlement.

IT is stated that the French cable company has accepted the terms of the rival companies' agreement, subject to ratifications by French and American governments.

THE defeat of Ayoub Khan, according to reports from Simla, caused Ameer Abdurrahman Khan the greatest satisfaction, and has had the most quieting effect on the country.

THE upper portion of Plymouth Rock, which has laid for 46 years in front of Pilgrim Hall, at Plymouth, has been returned unostentatiously to its original place beside the Rock itself.

MR. RUSKIN gives some sensible advice with regard to the proper and unstrained education of children. He says: Make your children happy in their youth; let distinction come to them, if it will, after well-spent and well-remembered years; but let them now break and eat the bread of heaven with gladness and eagerness of heart, and send portions to them for whom nothing is prepared; and so heaven send you its grace before meat, and after it.

Bay Horse District.

A correspondent of the Salt Lake Tribune, writing from Challis, Idaho, says: A ride of eight miles in a southwesterly direction from this place reaches the mining district known as Bay Horse. In making the journey, we travel up a good mountain road until a point high up is reached, when, taking a trail, we climb to the summit of a high divide, from which the view of the surrounding country is vast and full of grandeur. From this dizzy height, the Salmon river and its course is observable for nearly 100 miles.

The first mine reached is that called Bull of the Woods, owned by Riley & Sullivan, who are taking out ore and sacking it for shipment to the new smelter. This mine, as all others in the district, is in elate formation, but has a foot-wall of porphyry. The ledge lies at an angle of 45°, dipping west, and the ore assays very high, the average running up to from \$600 to \$800 per ton, and smelts easily. The elevation of the present workings is 9,500 ft. above sea level.

A short distance from this is located the most noted mine of this locality, called the Ram's Horn. The ledge, varying in width from 3 to 12 ft., lies at an angle of 30°, and cuts through the hill of slate, and has been traced and located for several miles south, extending into the district known as Poverty Flat. The present work on the Ram's Horn consists of one tunnel 355 ft., and another 150 ft. Another tunnel of 80 ft. has been run in on another ledge that seems to be an offshoot of the main lode. The ore is chloride carrying 16% lead, and when sampled the first grade runs 500 ounces and the second grade 140, and carries some iron and copper. The ore is sent down the steep and rugged sides by means of a 700-ft. tramway of T rails, operating the cars by means of iron ropes and a middle turn out. This property is considered one of the best in the entire district, and is owned by Col. M. E. Lindeay, A. J. McNah, G. S. Fisher and E. W. Jones. Mining is being prosecuted with a force of 45 men, and ore is shipped to the smelter at Bay Horse, some three miles down the gulch.

Some distance up the Bay Horse creek, some small lakes add much to the beauty of the scenery, and a visit to the largest one proved it to be apparently bottomless and its waters abounding in fine trout. Going down the creek the town of Bay Horse is reached, where it stands nestled in a narrow valley, hemmed in by high and precipitous mountains. A saw mill and smelter are the attractions to induce settlers here.

The Bay Horse smelter just started is known and operated by the Omaha Smelting and Refining Co. of Omaha, Nebraska, and is capable of handling thirty tons of ore per day. The officers of the association are: C. W. Mead, President; E. W. Nash, Superintendent; A. J. Cook, manager of the smelter and G. P. Monton, manager of the mines. The Omaha works paid last year nearly \$7,000,000 for ores, a large portion of which went from Utah and Idaho, and their getting a foothold here with a smelter of such capacity and with chances of enlargement, will do very much toward developing this new and important district.

Half a mile from the smelter we entered the Beardsley mine, owned by Robert Beardsley & Co. The lode is in limestone, with a slate talc hanging wall. The vein varies in thickness from three to twelve feet, and runs high in silver in selected specimens, while the entire lode goes above 60 ounces in silver and 25% lead. The mine is valued at \$200,000, and is certainly favorably located.

So far the town of Bay Horse is but of little interest, except as a new mining camp where, within the past two months mill machinery and a dozen houses have been built, and people have congregated to the number of about seventy-five, all intent on making money. A good wagon road connects that road with Challis.

A THRIVING MINING CAMP.—Rich discoveries continue to be made in El Dorado canyon, San Bernardino county. A correspondent of a San Bernardino paper, writing from that camp, says: We have visitors who desire to hold our mines, but as long as we are taking out rich ore and plenty more in sight, we want to see the cash if we dispose of our claims. We struck an 18-inch ledge of ore that assays \$416 per ton. A contract has been let on the Silver Eagle to run a tunnel 50 ft. Work has been commenced on the January mine. The ledge is from 6 to 40 ft. wide. The ore so far taken from it assays from \$100 to \$300 per ton. Men are arriving here every day, and I believe there will be a camp of 500 men here in less than two months. Mr. Philib, the Raymond & Ely Superintendent, has returned from California. He has bonded a mine for \$10,000 and will commence work on it immediately. Weaver is still sinking on the Lone Star mine, and taking out ore that will assay \$1,000. The streak is only eight inches wide. Nicholls, Howell and Varneke are at work on their claim, and are taking out horn silver ore that so far has assayed \$5,860 per ton.

SILVER CITY (New Mexico) is looking forward to a prosperous season this fall and winter. Bremen's mill is running steadily on rich ores. The Legal Tender mill will soon be completed, and will commence on a large pile of ore now on the dump. The Cosette mining company is now repairing the old Lyon mill and will start up as soon as the repairs are completed.

Some fine sunny offices (next to the PRESS office), to rent (at very reasonable rates), by Dewey & Co., at 202 Sansome street, corner of Pine.

Quinine and Arsenic

Form the basis of many of the Agree Remedies in the market, and are the last resort of physicians and people who know no better medicine to employ for this distressing complaint. The effects of either of these drugs are destructive to the system, producing headache, intestinal disorders, vertigo, dizziness, ringing in the ears, and depression of the constitutional health. ATRE'S AGUE CURE is a vegetable discovery, containing neither quinine, arsenic, nor any deleterious ingredient, and is an infallible and rapid cure for every form of Fever and Ague. Its effects are permanent and certain, and no injury can result from its use. Besides being a positive cure for Fever and ague in all its forms, it is also a superior remedy for Liver Complaints. It is an excellent tonic and preventive as well as cure, of all complaints peculiar to malarious marshy and miasmatic districts. By direct action on the liver and biliary apparatus, it stimulates the system to a vigorous, healthy condition.

FOR SALE BY ALL DEALERS

Judicious Advertising.

We find in the Joliet Sun the following sensible remarks in regard to advertising: "Last Sunday's St. Louis Globe-Democrat contained fifty-three columns of advertisements. Most of this space was taken by old, well-established houses—the very ones that might have some grounds for saying: 'Oh, everybody knows we are here. The New York Herald of the Sunday previous contained 105 columns of advertisements, for which its receipts were \$11,000. One of the leading and best known dry goods houses of that city took four columns. When successful business men of vast experience and so well known that their names have become household words, keep up their advertising from year to year at enormous expense, they must certainly believe that judicious advertising pays."

Pocket Mining Atlas,

Containing the principal mining districts in the United States. Compiled from the latest official surveys and the most authentic sources by Edwin Bolitho. Sent, post-paid, on receipt of \$1. Address, Dewey & Co., 202 Sansome St., S. F.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omissions of agents.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for \$3 per (half-yearly) volume. In cloth and leather binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus, terms of subscription, etc., and request that they circulate the copy sent.

INVENTORS, and others interested, will receive DEWEY & Co.'s MINING AND SCIENTIFIC PRESS PATENT AGENCY Circular free on application at this office. It contains 42 pages of hints and information about Patents, Patent Laws, Patent Office Regulations, and how to obtain valid patents.

HOW TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the PACIFIC RURAL PRESS, which we will sell for \$3 per (half-yearly) volume. In cloth and leather binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

J. G. COLMERN is requested to report to this office. He went to Humboldt County, Cal., about May 4th, 1880. His Agency for this paper has been revoked for good and sufficient reasons. Mr. O. is a heavy set man, of dark complexion, weighing some 175 pounds, or more.

CHEW JACKSON'S BEST SWEST Navy Tobacco.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

DIVIDEND NOTICE.

OFFICE OF THE

Napa Consolidated Quicksilver Mining Co.

SAN FRANCISCO, SEPTEMBER 21, 1880.

At a meeting of the Board or Directors of the above named Company, held this day, a dividend (No. 13) of Ten (10) Cents per share was declared, payable on WEDNESDAY, the 22d day of September, 1880, at the office of the Company, Room 16, Academy Building, No. 350 Pine street, San Francisco, California.

WM. W. FARRISH, Secretary.

ANNUAL MEETING.

The regular annual meeting of the stockholders of the Spaulding Gold and Silver Mining Company will be held at the office of the Company, No. 117 Battery street, San Francisco, California, on TUESDAY, the Twelfth (12) day of October, 1880, at the hour of 2 P. M., for the purpose of electing a Board of Directors to serve for the ensuing year, and for the transaction of such other business as may properly come before the meeting. Transfer books will close on Friday, the Eighth (8) day of October, at 12 o'clock M., until after the meeting.

JOHN HEIN, Secretary, Office—No. 117 Battery street, San Francisco, Cal.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts

FRUE'S ORE CONCENTRATOR OR VANNER.
Plunger Jigs. Revolving Screens.
CRUSHING ROLLERS. SAMPLE GRINDERS.

Hoisting and Pumping Machinery.

STEIGER & KERR'S CONTINUOUS DISCHARGE AND GRINDING PAN.

This pan is designed to receive ore direct from a rock breaker, and reduce it to the fineness necessary for amalgamation, thus taking the place of the ordinary stamp battery. The cost of this Mill places it within the reach of all; and one point of advantage not to be overlooked is the fact that the cost of erection, which adds so much to the expense of the stamp mill, after it leaves the foundry is, in this case, reduced to a fraction, as the mill is complete in itself, and requires no expensive foundations, bed logs, battery frames, etc., but can be placed in position in a few hours after it arrives on the ground, without the aid of skilled labor. This simple arrangement, durable as it is simple, is a most important improvement in the working of gold ores, as it enables parties to construct and erect a mill at half the cost of a stamp mill, and with a great saving of time, and size of mill building. Each pan is capable of reducing 10 tons of average ore in 24 hours, the ore being first broken in a rock breaker, small enough to go through a half-inch screen. There is an important point in the action of this Mill, to which we desire to call the attention of miners and millmen. We allude to the grinding and scouring action on the gold before it is discharged. The value of this point cannot be over estimated, and it is not necessary to do more than mention the fact, as it will be at once recognized by all competent millmen who examine the pan in operation, and especially by those who have had to deal with tarnished or rusty gold, as it is commonly called, and which is often encountered in our mines, and which is such a cause of loss. The plan of feeding is the same as in the stamp mill, either an ore feeder or hand feeding being adopted, as may be desired. Parties interested in mining and mills can see the Pan in operation by calling at the OCCIDENTAL FOUNDRY, STEIGER & KERR, 137 First St., S. F.

MOREY & SPERRY,

MANUFACTURERS OF

Gold and Silver Grinding and Amalgamating Machinery

HOWLAND'S PULVERIZER Takes the Place of the Cumber-
some Stamp Mill and can be put up in one day ready for work.

IT HAS BEEN FULLY PROVED AND TESTED.

It weighs complete, 7,000 pounds. It costs \$1,250 ready for the belt. Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chlorinating Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies, Iron Work complete for Wood Frames, also

SPERRY'S
WROUGHT IRON FRAME

FOR STAMP MILLS.

Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores, Wet or Dry Crushing Mortars.

MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

GIANT POWDER

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-OLYGERINE PATENTS.

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive

Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. Triple Force Caps and all Grades of Fuse.

The Kropff Ice Machine.

Machines for the production of artificial cold can be divided into two general classes; first, those in which cold is obtained by the expansion of compressed gases; second, those in which cold is obtained by the evaporation of fluid. The machines of the second class employ the evaporation of fluids, such as ammonia, ether, methylic ether, sulphuric acid, anhydrous sulphurous oxide and other chemical substances. These machines are worked either upon the principle of compression or of absorption, the

supply the cellars with immense quantities of pure, cold and dry air, furnishing either all at the same time, or each singly, according to the capacity of the machine. The machine supplies thereby cold for every process requiring cold, whether it be ice for storage in the ice-house or for use in the fermenting tubs, or water for cooling the wort, or air for keeping the fermenting and store-cellars at the required low temperature. By his system the ice machine sends cold to all parts of a brewery; so that it really becomes the heart of the same.

In the Kropff ammonia absorption machine the ammonia vapors are separated in the boiler by the action of the steam, condensed in the

ammonia boiler; B, the condenser and absorber; C, C, the ice making tanks; D, the cold-water tank; and E, the air-cooler.

If cold air is desired for the cellars, the same is cooled to a low temperature in the patent air-cooler by cold water or brine, refrigerated in the cold-water or brine tank. The air-cooler consists of a series of cylinders, through which the air is successively forced, it working its way through sprays of ice water or brine. The sprays are formed by the passage of the cooling liquid through perforated plates at the top of each cylinder. Connecting tubes pass from the upper part of one cylinder to the lower part of the next, and conduct thereby the air from one

\$5,500, produces 200 pounds of ice per hour, requiring one horse-power to operate it.

The machines give pure, dry and cold air for cellars. They are manufactured in Nordhausen, Germany. Paul Goepel, Tyron Row, New York, is agent for the United States. The machines are in use in many of the large European breweries. In this country there is one at George Ringler & Co.'s, East Ninety-Second St., New York, and one at Weher & Schilling's, Louisville, Ky. The machine illustrated is specially adapted for brewers' use, but they are equally well adapted for other purposes. Either, for producing ice for mines, or for cooling air to be forced into mines, they may be

THE KROPFF AMMONIA ICE MACHINE AND AIR COOLER.

former system requiring considerable power, to wit: steam and coal, while the latter system requires less power, but a considerable quantity of water for cooling. Owing to the small running expenses and reliable working of the absorption machines, they have given satisfaction where introduced. Amongst all ice machines which employ chemicals, the greatest number now in use employ ammonia as the refrigerating agent, which has the advantage that it can be more cheaply and easily obtained than any other.

Prominent among the manufacturers of ice machines has been Oscar Kropff, of Nordhausen, in Germany, who has made for himself a world-wide reputation for substantial and durable work, and more especially for the manner in which he has adapted his machine to all the different forms of cold required in the brewing processes. His machine is an ammonia machine, built on the principle of absorption, but with all the improvements, which an experience of 20 years has suggested. His machine enables the brewer not only to make ice, but also to cool large bodies of water to a low temperature and

cooling coils into liquid form, the liquid ammonia being collected in small vessels, from which it is conveyed to the ice-producers in which the water is frozen into slabs of oblong shape. The low temperature is produced by the quick evaporation of the liquid ammonia in the coils of the ice-producers, whereby heat is abstracted from the surroundings and thereby intense cold produced. The ammonia vapors are returned to the absorber, where they are brought into contact with the water from the boiler, which is poor in ammonia. This water absorbs the vapors and is then pumped back again into the boiler to be used over and over again in the same manner.

In the engraving given herewith this machine is shown in connection with the ice-producers, cold-water tank and air-cooling apparatus. The liquid ammonia is conducted to the ice-producers and cold-water tank, so as to make ice and cold water, which latter is conducted off, to be used for cooling the wort in the wort-coolers, or the beer in the fermenting tubs. A pump returns the water to the tank to be again refrigerated for use. In the engraving, A represents the

cylinder to the other. A continuous supply of pure, perfectly dry and fresh air of very low temperature is thus furnished, by which the different processes in brewing are advantageously effected.

By the use of the air cooler the cellars can be kept uniformly and without difficulty at the required low temperature. The air is distributed in the cellars by flues or tubes, which pass along the center of the cellars, and which are provided with openings, closed by slides, so as to keep the supply of air within perfect control. This air cooler has been recently patented in the United States (May 18th, 1880.) It can also be run with ice water, and in this form is an economical means of cooling the cellars of such breweries which do not like to go to the expense of an ice machine. An air cooler alone, with refrigerating tank, fan and pump, but without the ice machine, costs from \$1,200 to \$4,500, according to size. The ice machine itself costs from \$5,500 to \$20,000. The \$1,200 air cooler requires a quarter of a horse-power to run it, and will cool 25,000 cubic ft. to 32° F. per hour. The smallest sized ice machine, which costs

used. There are five sizes of the air cooler, the largest costing \$4,500, and being capable of cooling 650,000 cubic ft. of air per hour to a temperature of 32° F. The \$20,000 ice machine produces a ton of ice per hour. Mr. Goepel will furnish estimates and give more detailed information on application.

MANAGERS OF CORPORATIONS.—In the case of McKiernan vs. Leuzen, the Supreme Court has decided that when a corporation is endowed by its charter with the capacity to enter into any obligation or contract, essential for its purposes or for the transaction of its ordinary affairs, and its business is transacted by a general managing agent, who is suffered to exercise general authority in respect to its business, the corporation is bound by his acts, within the scope of the powers assumed by him, in the same manner as if expressly granted. In respect to the management of its business, a general managing agent and superintendent is the representative of the corporation, and may do in the transaction of its ordinary affairs, what the corporation itself could do within the scope of its powers

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EWS

Mineral King, Tulare County.

New Ledges—New Fossils.

EDITORS PRESS:—The crucial test for the Mineral King mining district has now been fully made. The vital question for success in extracting the silver and gold that certainly exist here in large quantities in the numerous metallic veins of these vast igneous, aqueous and metamorphic rock masses, is solved practically and, no doubt, conclusively. That question, as already indicated, is:

Do the Mineral King Mines Produce Free Milling Ores?

Mr. Fowler's Empire mill has decided this for the district, by an experimental run of not quite three days' full time, more than six weeks since. The whole working of the machinery was satisfactory, showing that the preparations were thorough. In all, the stamps ran only between two and three days. After this short run a careful clean-up was made, to learn results and to decide whether it will pay to run the mill without previous treatment of the ore by roasting or other process. Much amalgam was obtained. Little or no quicksilver had been wasted. When this amalgam was reduced to bullion, with the greatest care and skill, the result obtained was a bar of bullion 10½ inches long, 5 inches deep and between 4 and 5 inches wide—the first born, as a full-sized silver bullion brick, to which Mineral King, or, in fact, Tulare county, has given birth. At the time of that experiment your correspondent, in company with R. B. Harper, superintendent, John Dunn, chief engineer, and Robert Steingger, assayer, saw this bar weighed by S. Scribner, amalgamator. It was 86½ lbs., which, at 14.58 oz. per lb. for Troy weight, gave 1,261.17 oz. Its value in money has never been made public, but, as some lead remained in spite of the careful process of reduction followed, there was probably less than \$1,000 silver in the bar.

Your correspondent has, however, been reliably informed that only about 38% of the silver in the ore was extracted by this milling process alone. Mr. Harper, the Superintendent, was at once convinced that the ore must be roasted before milling. Mr. Fowler made his arrangements accordingly, and the time since then has been occupied in preparing the fire-proof and other brick; and in erecting the roaster. Mr. Harper has been aided in this important work, recently, by C. A. Luckhardt, the noted mining engineer. Another experimental run has lately been made, and Mr. Luckhardt is reported as being well satisfied with the result. Meanwhile, the recent developments in the mine from the extension of the winze, are full of encouragements. Large bodies of rich ore are reported to have been discovered. These matters indicate (and we trust without any farther disappointing delay) the successful development at last of the Empire mine. May it and neighboring mines yet have a long era of prosperity.

In this connection it may be of service to mines requiring roasters like that now built for the Empire, or smelting works, as most Mineral King ledges require, to record a suggestion given me by an experienced miner recently. It is to

Use Soapstone Instead of Fire Brick—

A good quality that does not scale; lasts in copper smelting works six months, where common fire-brick will last only three or four weeks. It can be easily sawn of any size required. Where it can be used, there is certainly economy in it. Now, as there are masses of the very finest quality of smooth greenish soapstone in the Mineral King district, it may be used to great advantage there for future smelting works.

A New Mining Region.

To which no attention has yet been called in your columns, is as follows: About 40 miles south of Miner's peak, and on the same ridge, is a sharp granite peak, five or six miles east of the sources of Deer creek and White river. On the map it is called "Smidday peak." It is likely to become noted for its gold and silver mines in the future. Within the last year ledges rich in free gold and sulphurets have been located around its base, and much "float," rich in free gold, has been discovered southeast of it, towards the Kern. On one vein a tunnel has been run in 90 ft. Assays range from \$24 per ton into the hundreds. It is deemed likely that good placer diggings exist east of Smidday peak on a small tributary of the Kern. The district is in the southern edge of Tulare county, and can be best reached from Greenville by road and trail in a distance of 25 or 30 miles.

No information has yet been given your readers of a promising ledge in Deer canyon, three or four miles northwest of the town of Mineral King. It is

The Double Standard.

Your correspondent visited it while there, by trail through Farewell gap, in company with Stephen Barton, former editor of the *Iron Age*, Visalia, and W. B. Wallace, who own it jointly with F. J. Walker, present editor of the *Delta*. The ledge is several feet wide, has been prospected some distance by shaft and drift, and its ores assay from \$3 to \$500 per ton.

By Mr. Barton and Dr. S. G. Gsorge my attention was called to some

Interesting Fossil Impressions

On shales and slates found in Lake canyon. Dr. George and I visited their locality while on a trip to a promising ledge of his near Crystal lake at the head of the canyon, and which he calls "Silver Wreath mine." These fossiliferous rocks, the only ones yet found in all that district, are on a steep declivity among some stunted junipers on the left of the trail, a short distance beyond the Mogul ledge. Large masses of these shales and slates are found standing on edge in almost perpendicular positions. The impressions appear to be those of fucoids, bivalve shells and small crustaceans. They certainly bear a close resemblance to some of the primitive vegetable and animal forms of the silurian age. I sent some to Prof. Joseph Le Conte for his ripe and decisive opinion, and Dr. George sent some to Mr. Hanks, State Mineralogist.

Prof. Le Conte decides that they belong to the triassic or jurassic—most likely the former. He informs me that similar ones have been sent to University Museum from Plumas county. They are some of the most primitive fossils yet found in California, and though they do not go back to the paleozoic or oldest fossil-bearing era, they belong to the mesozoic, or next oldest.

J. W. A. W.

Hanford, Sept. 25th.

Auriferous Gravel.

A Theory of Its Formation.

EDITORS PRESS:—As I have examined and studied in the rocks, and more particularly the gravel deposits of California for many years, I have eventually arrived at certain conclusions, which may be novel to some:

I have noticed in the PRESS from time to time the various ideas and theories, as set forth by different writers, according to their fancy, imagination, or power and ability to look back into the past, and examine the works of nature, as they were going on millions of years ago, the same as they are to-day.

Many errors and false ideas have been presented to the public, and particularly to the miners, about the origin and production of the auriferous gravel deposits of California. These have often led the miner, and more particularly the prospector, astray. In other words, the miner has not received that guidance and assistance the State should have rendered him years ago.

There was a time when the Sierra Nevada was but a low mountain range, and the waves of the Pacific beat against its foothills, which probably were not extending southwest and northeast as now; but rather north-northwest and south-southeast, parallel with the main mountain range, with deep and parallel depressions between.

The drainage of the waters from the land carried with it a large amount of sediment into the valleys of the sea. The result of this sedimentary formation was the secondary or metamorphic rock. In course of time, the molding, modeling and remodeling of the face of this secondary formation became land interspersed with large dykes of trap, which was born in the sea, on lines parallel to the main mountain range. During those changes, the face of the earth had been subjected at times to great convulsions; many fissures were formed in its crust, some small, and some of great magnitude, extending through the secondary and down into the primitive rocks. Minerals in solution, with silica predominating, formed and crystallized in those fissures till they were full. These are now known as quartz veins, or lodes.

As land in places acquired an altitude above the sea level, rivers took their inception from the rains that fell upon the land, and became extensive according to the dimensions of the land, and ran in various channels from the summit of the Sierra to the deep Sacramento and San Joaquin depressions, which were then covered by the sea. These rivers were deepened and enlarged by time, according to the elevation of the country. In the early period, the land attained but a moderate altitude, which in all cases governs the depth of the river channels, so that the river beds of the ancient channels were only about from 400 to 800 ft. lower than the surrounding country. By degrees, and in time, as all the different streams, with their tributaries, had formed their channels, the Coast range, with all the land adjacent thereto on the east, made its appearance above these, and the waters receded. By the slow and gradual upheaval, all the mountain streams from the Sierra Nevada and westward, began to lose grade, and a deluvial deposit, formed from boulders and gravel mixed with more or less gold from the breaking down of quartz veins, began to gather along the bottom of the channels, as the stream was no longer rapid enough to carry it away, particularly so on the soft, slaty bedrock of the auriferous belts. Much of this material was the result of erections by tributary streams, of whatever size, yet they contributed by crossing and wearing down by slow degrees the various auriferous belts, which are three in number in the central part of the State. Time and ages were passing on gradually as the coast was rising; so the inland rivers kept filling until the gravel deposit attained a depth of from 200 to 500 ft. The streams were

then flat and wide, and meandering from side to side; by times, undermining the low river banks, and dropping the then growing trees into the stream, of which we now find large quantities in the form of fossil wood, mostly in the upper strata of gravel from 50 ft. to 100 ft. in depth. This fossil wood affords positive proof that a fine country and magnificent forest existed on the Pacific slope ages ago.

We have abundant evidence all over the central part of California of the presence of these ancient river systems, which are now so conspicuous and valuable, one of which covers, to a large extent, the counties of El Dorado, Placer, Nevada, Sierra and Yuba. These river systems cutting for ages by slow degrees down through auriferous belts of rock, which are in many places literally streaked with quartz veins, must have separated an immense amount of gold from this quartz veins, in which it was formed, and carried the greater part of it into the Sacramento valley or basin. This theory applies equally well to other drainage basins, which exist from El Dorado county and south, as far as the upper San Joaquin, and others further north emptied into the upper Sacramento.

There is also reason to believe that during the first geological epoch of this State, the formation of these rivers was greatly facilitated by glacial action. During the early part of this period, one of those streams in its course westward, cut through a very extensive trap-rock belt at Dutch Flat. The channel became deep and narrow comparatively. The river had but little gravel in it at the time, when all of a sudden, a great mass of rock appears to have slid from the south bank into this stream, and we find that a great portion of this slide—millions of tons—was carried westward, down stream, three or four miles in a body, without being washed or rounded by the action of the water. I take this as evidence of glacial action.

Some time after this great slide, the glacial marks disappear, and the rivers having lost most of their grade, still kept on filling up 200 or 300 ft. more, with small uniform gravel, varied by little sand streaks, and the face of the country became nearly level, the streams meandering from side to side in the valleys, which were gradually being formed.

During all this time there was no lava on the west of the Sierras; but gradually a new scene appeared on the face of this slope. The earth shook and trembled by reason of internal convulsions; great fissures opened, large quantities of ashes issued therefrom, which flowed down from the volcanic Sierras into the valleys below. The stream ran so level, that a large amount of ashes was deposited over the whole length and width, from 100 to 200 ft. in depth. After this first deposit of ashes came the heavier and more solid earthy material, generally known as lava, which issued from time to time in immense quantities from numerous volcanoes which came into existence near and above the line of the Sierras. It was doubtless the action of these volcanoes which entirely obliterated the ancient river system of the central and northern part of California. This great volcanic eruption kept on for a long period of time, flowing lava and ashes in different places and at different times, till it covered nearly the whole slope, from the summit to the present valleys, to a depth of from 200 to 1,000 ft. During this period there was no fixed or permanent bed for any stream. All streams were liable to be filled with lava at any time, and the running waters had to form new channels repeatedly. Eventually, when the disturbing elements became exhausted and quiet prevailed, the new and present river system began to form, and the present rivers took their inception from the natural downward tendency of the water.

From that time till now, the country has changed greatly in altitude, and attained, generally, a much greater altitude than it formerly had, which is clearly shown by numerous faults in the bedrock, and also by the disturbances, in various places, of deluvial and volcanic strata of horizontal formations. One particular proof of upheaval which exists in the Sierra Nevada, I cannot refrain from pointing out. It is to be found in the form of an immense gravel, or boulder and deluvial deposit on the summit of the Sierra Nevada, three or four miles westward from Webber lake. All this deluvium is formed from basaltic rock at an altitude of about 8,000 ft. This is proof of a large stream, once flowing westward through that section of country, and draining a large portion of the interior basin in the earlier part of the modern river system. From this great and irregular upheaval we have two notable results: First, the waters running with great velocity have cut down all those mountain streams into the form of deep gorges or canyons. Secondly, it has destroyed the regularity of grade in all the ancient river channels, and this result appears to be a great stumbling block in the way of tracing out those ancient streams. Nevertheless, the streams did run from the whole upper part of El Dorado county, northwest and through Placer and part of Nevada, and down into the valley in Yuba county, receiving many tributaries on the way, from the east, northeast and north. Many of these streams can be found and traced, where the ancient channels have been cut through by the modern streams and canyons. And these same cutting and wearing down processes have contributed or furnished most of the gold which we find in the modern river beds, partly from the ancient gravel beds and partly from wearing down the auriferous belts of rocks and quartz veins to a depth of from 1,200 to 1,500 ft. lower than the ancient streams ran. But in the early period of the modern streams,

they contained no auriferous deposits because they ran in lava, and it not being gold-bearing, there was no gold mixed with the gravel in those streams till they had cut down and through the ancient river channels, which had previously become obliterated by the flow of lava. It is of the greatest importance to the prospector and miner to notice and understand this fact, because in the early gravel deposits formed from lava material, he will never find gold enough to pay for extracting. But after they had cut down through the ancient gravel channels, then still deeper down through the bedrock and gold-bearing quartz veins, they became rich in gold and hence have paid so well to work. L.

McMillen District.

This camp is "built upon a rock," upon several of them in fact, assaying enough to keep town lots at a premium. Mines are located in it and around it, and its principal business street is included in the boundaries of a claim. Its people too assay 'way up in hospitality, and the stranger will find himself well treated, and when in less favored spots will retain admiring recollections of rich ledges and pleasant memories of McMillen good fellowship. The camp is 21 miles from Globe, a little east of north, in a canyon winding north for a mile and then turning to the east. Including Stonewall mill and camp, there are between 45 and 50 buildings of adobe and frame. The principal business houses are Killner & Co., whose affairs here are in charge of Mr. J. W. Ranson, a thorough business man; Mr. Nicholls, who is one of the first merchants in the place, and Mr. Strong, in whose establishment is located the Postoffice. Mr. F. C. Minshull has one of the most complete news depots in the country, well supplied with periodicals from every part of the world. He also carries a good stock of liquors, stationery, notions, drugs, etc. Messrs. Martin, Hoffman & J. N. King represent the saloon business, and a good butcher shop, barber and laundry are flourishing. The Merchants' Exchange and Stanley House are the two hotels.

Mining is distinctively the industry and life of the camp, employees from mines and mills being the best customers. To mention half the good claims in this vicinity would require an extra edition, and we will confine ourselves to only a few of the most prominent, which a hurried trip enabled us to visit. The Stonewall is of course the one engaging public attention most at present, both on account of extensive development and wonderful richness. This claim has justly a more than territorial reputation, and the steadily increasing value of its ore as depth is attained is proof of the permanency of our ledges. At a depth of 480 ft. a large body of water was encountered pouring in in each volume that half the 24 hours was consumed in pumping it. New and improved hoisting works are now on the ground being erected, and the mill will hereafter be run regularly, this abundant supply of water removing the only obstacle they have heretofore encountered in making full time.

The Lee mine, joining the Stonewall on the southwest, has a shaft 80 ft. in depth, and crosscut of 84 ft., showing ledge to be 68 ft. in width. There are several drifts along the footwall and two winzes, one on the foot wall and one near hanging wall. Work will be resumed soon.

The Mayflower lies northwest of the Stonewall, and shows little more than assessment work. A ton of ore from this claim, worked at Silver City three years ago, returned \$3,000.

The 4-40, an extension of the Florence, shows a ledge of four ft. in width, running parallel with the Stonewall and Lee. This property has been leased to different parties, but never thoroughly developed.

The Antler and Washington are owned by James Wilson, of New York. The former has a shaft 150 ft. deep, and drifts are now being run. The ledge shows four ft. in width, carrying exceedingly rich ore. Steam hoisting works are in operation on the mine.

The second north extension of Stonewall is the Washington, with two shafts, 40 and 50 ft., exposing a well-defined ledge of high-grade ore. Hoisting works are required here before work can be prosecuted.

The Democrat, located by Flournoy and Aiken, and now owned by a New York company, is coming to the front. The working shaft is down 70 ft. on a two and a half ft. vein of rich chloride and horn silver. There are four veins running parallel and dipping north, on which are eight cuts and prospect shafts. Ore from the bottom of working shaft assays \$150, and \$20,000 was taken out by first owners, just where it was richest and could be most easily secured. The present working is the first systematic development that has been attempted, and Mr. Charles D. Spain, Superintendent, is going ahead rapidly, and in a business-like manner. He is evidently the right man in the right place.

There is very little "hurrah" and no fuse and feather about McMillen. It is going on in its own quiet and prosperous way, and is not only supporting, but the influence of its bullion shipments and traffic is felt all over the county. —Globe Chronicle.

The mines around Shauntie, Utah, are said to be looking well. The prospects for a boom in that district are bright, and the men who reside there and own claims that they have 'staid by' for 10 to 15 years expect to realize handsomely from ore shipments this fall.

MECHANICAL PROGRESS.

A Queer Locomotive.

In our last issue we gave some account, under the above head, of a locomotive with its driving wheels on top—or rather with two sets of driving wheels, one vertically over the other. This locomotive is now in process of construction at the Grant Locomotive Works, in Patterson, New Jersey. We have since met with the following additional particulars in regard to this singularly constructed machine, which presents the first really radical departure in locomotive building since the days of Stephenson. We copy from the *New York Times*:

As is generally known, all devices hitherto employed to gain speed have in some way depended upon an increase in the size of the driving wheels, or of the number of strokes of the piston, to both of which methods there are well-known practical limits and objections. This invention is intended to utilize the familiar principle in mechanics, that when a large wheel drives a small one there is a gain in speed and a loss in power. Speed being the object in this case the power is, therefore, transmitted from the piston to the track by a combination (on each side of the engine) of three wheels, one upper and two lower. The upper wheel is driven by the piston, the two lower wheels revolve around a common axle, but their diameters are unequal. The larger is five and one-half ft. in diameter (as also is the upper driving wheel), and the smaller one is four ft. The upper driving wheel, carrying much of the engine's weight, rests and acts on the smaller of the lower ones, and the larger of the lower wheels, which must turn with it, both being fixed to the same axle, transmits the power to the track. The theory is that, without increasing the oscillations of the piston above those now common, the revolutions of the larger of the lower driving wheels, and the speed of the engine will be increased in the ratio of the diameter of the larger wheel to the smaller, that is, in the proportion of five and one-half to four. There are also incidental advantages, such as great steadiness, arising from the fact that it is possible to carry the boiler very low; and there is an ingenious device for increasing at will the adhesion of the upper and lower driving-wheels (upon which the power of the engine depends) by forcing their treads together by means of levers operated by compressed air. The system of driving-wheels is, however, the head and front of the invention, which we have endeavored to describe without, in justice to the inventor, prejudging it.

REMARKABLE WELDING.—A correspondent of the *Blacksmith and Wheelwright* discourses as follows about welding:—"A great deal has been said about the welding of cast steel, and a great many different receipts for making welding preparations given, but for successful welding in my opinion there is nothing so good as the cherry heat welding compound. I have been a practical blacksmith and tool maker for over 40 years, and have used every receipt that I have seen printed and others that have not been printed, and I have yet to find its equal. If any there are who can say to the contrary, I would respectfully say that they do not know how to use it. For the information of such, I desire to state that although it is called cherry heat welding compound and you can weld with it at a very low heat, still I would recommend a borax heat or a little higher, and am satisfied that all blacksmiths using it in this way will be surprised at the results. Some wonderful things have been done with this compound. I will mention one which was exhibited at the American Institute fair, and was pronounced by the *Iron Age*, *Scientific American*, and other papers here and in Europe a wonderful piece of welding. A bar of Bessemer steel, $2\frac{1}{4}$ inches was bent over on itself, some compound put between and welded. The second weld was a piece of cast steel, $2\frac{1}{4}$ inches, welded back of the first weld on the same bar. The third weld on the same bar was a piece of blister steel the same thickness and width. Next a piece of iron same size, and the fifth weld was a piece of cast iron of the same size, $2\frac{1}{4}$ inches. The edge of the bar was then ground and polished and the welds were perfect. Many other remarkable things could be said about the above compound, but I will not encroach on your valuable space further."

STEEL joists are being made at a few factories in England and on the continent, but certain difficulties attend the rolling, which as yet prevents their manufacture on a large scale. Steel plates for bridges also are not as yet used to the extent anticipated, and the long span bridges in which their utility is undoubted, do not often occur. In boiler plates the considerable advantages which steel offers are being availed of, and for flanging and other treatment, where high quality Yorkshire iron was formerly used exclusively, steel is, says Messrs. Matheson & Grant in their half-yearly engineering trade report, found to be considerably cheaper, especially for plates of large dimensions.

Iron-Clad Steel—A New Manufacture.

The Norway iron works at their rolling mills in South Boston have been working a product of iron and steel lately which is somewhat of a curiosity to iron craftsmen. It is called, after working, iron-clad steel, and, although the process was invented and patented some years ago, it has never yet come into general use. It has always been considered rather difficult to work iron and steel together, to any great extent, on account of the difference between the two metals. Although steel and iron readily unite when they are brought to a proper degree of heat, yet it has always been found rather difficult to properly heat long bars of iron and steel so that they would become firmly welded together under the pressure of rollers. This invention of iron-clad steel, it is claimed, has surmounted the difficulty. The metals are united by a curious process before the rolling commences. A box is made of pig iron or muck bars, with sides, ends, top and bottom complete. Into this box the steel is put, the box is closed, the whole mass is brought to a high degree of heat, and the process of working begins. The iron box inclosing the steel, now in form of a solid mass with the iron and steel united, is worked into the form of a bar and is ready for rolling. This bar two or three inches square, it is claimed, costs three cents a pound. The process of rolling begins, and the steel with the iron outside of it can be rolled down into any size of rod or bar which may be desired. The most curious feature is that the iron and steel keep their places relatively, the iron still outside of the steel, no matter how much it may be worked.

Like the candy maker's plastic sugar when he puts in a lump of different color and draws and molds the two together, each color keeps its place and the stick of candy is produced with a red center; so the iron keeps its place outside of the steel in the process of rolling, and the steel is produced with a coating of iron around it varying in thickness according to the relative proportions of iron and steel that were used in making and rolling the box at first. As stated above, the process is not a new invention, but from the fact that the invention has lain comparatively idle for some time, it is probable that people interested in the working of iron and steel may have forgotten it, even if ever aware of its existence. The process of manufacture is curious, and several advantages are claimed over the ordinary process of uniting iron and steel by welding. It is claimed that the iron box prevents the decarbonizing of the steel in the process of heating and working. The superintendent of the rolling mills also says that the steel, which fuses at a lower degree of temperature than the iron around it, often bursts out of the iron enclosure in a molten state. It is proposed to put the iron-clad steel to various uses. It is already being made into horse shoes and tested, and it is thought that it may be very useful and available for other purposes. The article is controlled by a patent, and the rolling mills at South Boston produce only a prescribed amount for the company controlling the invention.—*Boston Herald*.

The Effect of High Speed of Engines Upon Condensation of Steam.

At the recent meeting of the Master Mechanics' Association, Mr. C. A. Smith, of St. Louis, reported the results of a series of experiments made to ascertain the temperature of steam cylinders during the working of the engine at varying speeds. The apparatus employed in these experiments consisted of a silver tube six inches long, 5-16 inches in diameter outside, and 1-32 inch thick, this tube being closed at one end, and having passed through it a rod connected by a cam and tooth gear to the index of an ordinary pressure gauge, the arrangement being such that the expansion and contraction of the silver tube moved the index of the gauge, and so indicated the temperature. The necessary graduations were obtained by the comparison of the instrument with a good thermometer. In using the apparatus it was applied to the cylinder, so that the exterior of the silver tube was exposed to the steam in the cylinder, and when thus applied to the cylinder of an engine working slowly, the index of the instrument showed during each stroke nearly the whole range of temperature to be expected from the variation in the pressure of the steam. At higher speeds, however, the range of action of the index became less. Thus on the 24th of April last the apparatus was applied to a locomotive hauling a light passenger train, the steam being throttled except at the highest speed. The experiments were continued through a run of 33 miles, and it was found that whereas, when the engine was making but 50 revolutions per minute, the instrument indicated a change of temperature of 120° during each stroke; at 100 revolutions per minute the variation dropped to 60°; at 200 revolutions to 30°; and 300 revolutions to 20°, the amount of variation being thus inversely proportional to the speed.

A NOVEL HORSESHOE.—A Berlin manufacturer is making a horseshoe of iron and hemp that is receiving considerable favor among the Germans. The shoe is of malleable iron carrying a deep wide groove, into which tarred hemp rope is firmly wedged. The rope is so thick that it protrudes beyond the rim of iron. The shoe is very light, and is said to be serviceable.

SCIENTIFIC PROGRESS.

Seeing by Electricity.

A correspondent of the *Scientific American* says that the device of "seeing by electricity" is not altogether new. The correspondent, W. E. Sawyer, of New York, writes as follows: "Early in the fall of 1877, the principles and even the apparatus for rendering visible objects at a distance through a single telegraphic wire were described at No. 21 Cortlandt street, New York, to James G. Smith, Esq., formerly superintendent of the Atlantic and Pacific Telegraph Co., and now of the Continental Telegraph Co., and to Messrs. Shaw & Baldwin, telegraphic constructors, now connected with the Continental. At that time the writer was engaged in perfecting an autographic telegraph by which maps and pictures were daily transmitted by telegraph over a single wire.

"The recent announcements of this discovery in three different directions, each undoubtedly independent of my own experiments, show how the same idea often occurs in separate minds. There is no likelihood of any plan of this kind ever being reduced to practice, for some of the difficulties in the way of all of the plans are insuperable, as will be apparent from the following reasons:

"1. The action of light upon selenium in changing its electric conductivity is slow; although new discoveries may remedy this feature.

"2. To convey with any accuracy an image, one even so small as to be projected upon a square inch of surface (I am speaking now of the apparatus you describe), would necessitate that this surface should be composed of at least 10,000 insulated selenium points, connected with as many insulated wires leading to the receiving instrument; for the variation of the 100th of an inch either way will 'throw a line out of joint.'

"3. The most delicate apparatus would not indicate a change in resistance by the projection of light upon merely a selenium point.

"4. Isochronism is unattainable, as required. The method I proposed involved the isochronous movement of the separate instruments. The transmitter consisted of a coil of fine selenium wire in a darkened case, having a diameter of say three inches. Light from the image to be transmitted was to be let into the chamber and upon the selenium coil by a fine tube which, starting at the periphery of the circle, would draw concentric imaginary spiral lines until reaching the center of the circle. Thus light emitted or reflected from the image to be transmitted would effect the selenium just in proportion to the brightness of the image at the different points within the compass of the circle traversed by the imaginary lines drawn by the opening in the tube.

"The receiver consisted of a darkened tube, having an inside diameter of three inches (corresponding to the transmitting circle) with its sides and bottoms absolutely black. In this tube, describing imaginary lines just as the tube in the transmitter, was a blackened index carrying two fine insulated platinum points very close together connected with the secondary wire of a peculiar induction coil, the primary wire of which constituted a part of the main wire leading to the transmitter.

"The transmitting ray of light and the invisible index in the darkened receiving tube were to start at the periphery and describe their spiral motions in exact unison until the center should be reached, and the speed being sufficiently great it is obvious that as the first spark between the receiving platinum points would not have ceased to affect the retina until the last spark, with the index at center, would have been produced, an exact image of the object before the transmitter would be reproduced before the eye of the observer placed at the darkened chamber of the receiver.

"But the trouble is to make the selenium sufficiently active, and to get the isochronous motion."

AZOTINE—A NEW PRODUCT FROM WOOL.—The *Annales Industrielles* notes a new discovery by M. Heddehault, which consists in the separation of wool from cotton in rage and waste products in which these two textiles are mixed, by treating them with steam at a 150° C. under a pressure of five atmospheres. Under the influence of this temperature the wool is decomposed, fuses, and flows off into a lower receptacle, while the cotton, flax, and in fact all vegetable fiber, are unattacked. It is then only necessary to pound and wash the latter to obtain products containing no longer any traces of wool, and which are admirably adapted for bleaching and manufacturing into paper. The solution of wool, evaporated by dryness, has been named by the inventor *azotine*. Owing to the increase in value of mixed cotton and woolen rags thus treated, especially for paper making, the cost of the operation is virtually covered, and the new product—*azotine*—costs really nothing. This material which is completely soluble in water, and which contains all its nitrogen in a soluble form, is to be used, mixed with dried blood, as a fertilizer. The invention is said to be an important one, both for the paper making industry and for agriculture.

ENCOURAGING SCIENTIFIC RESEARCH.—M. Pasteur has received from the French government the sum of \$8,000, to assist him in continuing and completing his valuable investigations upon the contagious diseases of animals.

THE CORROSION OF IRON.—Air alone does not corrode iron. Therefore, by the elimination of aqueous vapor and carbonic acid from the interior of closed iron vessels, the iron is preserved. This principle can be utilized in many ways for preserving unused steam boilers by thoroughly closing all orifices, and by heat causing the aqueous vapor to evaporate. Bursly proposes a cheap and simple method, by taking advantage of the affinity which calcium chloride has for moisture. He lays a flat, open vessel containing the calcium chloride in the iron vessel, and the air is soon freed from all moisture. As soon as the calcium chloride is saturated with moisture, it is useless and requires renewing. Water alone is also harmless in contact with iron, and if the ordinary water of commerce were evaporated in a vessel properly arranged to allow the escape of the air driven from the heated water, and then condensed before being allowed to enter the steam generator, corrosion would be almost completely retarded. This is, of course, assuming that the water was free from all injurious ingredients liable to deposit. But even with water highly charged with suspended matter in solution, it would be well purified by the preliminary evaporation and condensation.

DRYING THE AIR FOR METALLURGICAL PURPOSES.—Every furnace manager has been taught by experience how considerably the working of his furnace is affected by the state of the weather, and notably by the amount of moisture in the atmosphere. According to *Iron*, Mr. W. H. Fryer, of Coleford, Gloucester, has determined this cause of irregularity and expense by drying, or "dessicating," the air previous to its being blown into the blast furnace, Bessemer converter, etc., as the case may happen to be. In practice, the air to be forced into the furnace or Bessemer converter is passed over sulphuric acid or chloride of calcium, so as to deprive the air of the vapor of water contained in it. The dessicating material is disposed in a chamber through which the air is passed, the particular arrangement depending upon the nature of the material employed (whether solid or liquid) and its dessicating and other properties, the essential conditions of the arrangement being that the dessicating material shall expose a large surface to the air, and that the capacity of the chamber shall be such that the air will travel through it at a sufficiently slow rate to insure the thorough action of the dessicating material upon it.

A PECULIAR VARIETY OF COAL.—Mr. A. Inostranef describes, in the *Neues Jahrbuch für Mineralogie*, a peculiar variety of coal which occurs in the northwestern banks of Lake Onega, Russia, in strata stated to belong to the Huronian formation. It differs in its physical, as well as its chemical, properties both from anthracite and graphite. Pure varieties show a strong metallic luster, which remains even after exposure to a dull red. Its hardness varies from 3.5 to 4, and its density at 4° C. is 1.841. It is highly hygroscopic, an analysis yielding: Carbon, 95.50; hydrogen, 0.40; nitrogen, 0.41; water, 7.76; and ash, 1.01. When free from water the percentage of carbon runs up to 98.11%, so that it is richer in carbon than anthracite, though it contains less hydrogen, no oxygen and much nitrogen. The "black earth" from Olonez is distinguished from graphite, which it resembles much, by the fact that it does not yield graphitic acid or "Brody's graphite" with a mixture of nitric and sulphuric acids, nor does it burn as rapidly as graphite.

TELEGRAPHIC INVENTIONS.—Mr. R. E. House, the veteran telegraph inventor, proposes to revolutionize telegraphy by his new instruments for transmitting, receiving and recording automatically, at the rate of from 250 to 300 words per minute. As 40 words per minute is a pretty good rate at present, it is evident that the new plan, if it proves successful, will not increase the demand for telegraph operators unless telegraphic business is vastly increased; a result, however, which is expected, as it is claimed that, by the House system, messages can be sent at about one-tenth the cost by the present Morse system.

FIXING A MIRROR IMAGE.—A German scientist has succeeded in obtaining a chemical composition, by means of which it is claimed a mirror image may be fixed and sold as a photograph. With this composition the mirror surface is painted and the back part of the mirror receives also a coating of oil. The mirror thus prepared is held before the person who is to be photographed. The oil coating evaporates, and the likeness of the person remains in natural colors on the light surface. The image so fixed is brought into a bath, and is exposed half an hour in the sunlight before delivery.

NEW MAGNETIC EXPERIMENTS.—M. Ader has performed some interesting experiments upon bodies which are slightly magnetic. He finds that elder pith is more sensitive than ordinary wood, paper, etc. With a Jamin magnet, sustaining a weight of 220 lbs., and provided with two small polar armatures, separated by an interval of .78 inch, he has been able to attract, at a distance of .118 inch, a pith ball of .02 inch, suspended by a thread. He has been able even to raise it, and when once attached to the magnet considerable force is necessary in order to remove it.

The New York Herald's Paris special says: A syndicate for the construction of the Panama canal was definitely formed Saturday. Mr. Seligman and Messrs. Louheyran and Denier are at the head of it. It has been ascertained that the cost will be much less than at first estimated. The emission of a loan for 400,000,000 francs will be made about October 20th.

LATEST DIVIDENDS-WITHIN THREE MONTHS

A LCCRY CAVE.—*Transcript*, Oct. 7: A few days since a large mass of earth came from the top of the tunnel in the Wimpup shaft, which is at Quaker hill, completely clogging the aperture. At first this accident was regarded as a calamity, but subsequent investigation inspires the belief that it was a fortunate circumstance. We are informed that from the appearance of the ground where it broke down, the miners think the tunnel extends along under the gravel channel, a fact hitherto unsuspected. Steps will at once be taken to demonstrate whether the supposition is correct or not.

A GOOD PICK OF ENGINEERING.—Last Saturday night the connection was made between the perpendicular shaft and upraise at the Murchie mine. The result demonstrated Mr. Eglebright's survey to have been very accurate, as the two met with a precision not often attained. This new shaft opens the mine at that point to a depth of 50 ft below the 800 level. The 200 ft below where the upraise shaft is now being trimmed and timbered.

STARK GRAYEL.—During the past summer (Joustra, Pendleton & Robinson have been engaged in searching for the gravel lead at Snow Point, being worked by Blackwell & Wand. They ran a tunnel into the ridge at a point south of the B. & W. mine. After getting in 200 ft they made an upraise which has just tapped a promising-looking deposit of pay gravel. Our informant says they have a prospect of opening a rich claim.

PLACER.

STARTED UP.—*Dutch Flat Forum*, Oct. 2: The difficulties met in getting all the machinery in working order in the cement mill, at the New Gold Run mine, have all been overcome, and the mill started up on Monday crushing cement.

EXTENSIVE WORKS.—We understand a San Francisco company propose putting in extensive works, in the way of undercurrents in the American river, this fall. This company has given Towle Bros. an order for 100,000 ft of cedar lumber for the purpose of building the undercurrents. This work will necessitate the employment of several men.

PLUMAS.

PAY GRAYEL.—*Plumas National*, Oct. 2: From Superintendent Johnson, of Eureka, we learn that the miners in the big shaft at Jamison have found pay gravel, but no bedrock as yet. Two pans showed a result of 50 cents. The shaft is over 200 ft deep, and it is thought that bottom will be reached in a short time. The company have expended considerable money, and the encouraging prospects are welcome. Should they prove this lead good, it would be the room for hundreds of miners.

NORTH FORK.—Mr. Sam. Ballou informs us that mining prospects are looking up in that region. The sale of the Savercool mine, and the building of a new 40-stamp mill by the new owners, will make business lively for a while and help the permanent prosperity of the section. It is probable that some other extensive sales of mining ground will soon be made.

BLACK ROCK.—*Granville Bulletin*, Sept. 29: Thos. McMurtry, of Clear creek, between Wolf creek and Big Meadows, was here on Saturday with some fine looking rock from his ledge. He has been prospecting for several years without success, but thinks he has been rewarded at last.

NEW MACHINERY.—R. M. Wilson, supervising engineer of the Plumas National mine, has arrived, and is superintending the erection of two concentrators and sulphur-saving machinery in the company's mill.

GOOD PROSPECT.—The Acadian company have struck another rich prospect in their shaft, which they are sinking.

SISKIYOU.

GRIZZLY GULCH.—*Yreka Journal*, Oct. 2: Bailey & Co. are still finding very rich quartz and a wide ledge, in sinking down at Grizzly gulch, on Indian creek, and several other parties have located claims in the vicinity. On the supposed extensions, Geo. Baker, Noah Williams, W. K. Lippert, Moses Jones and Hart & Thibault have staked out claims. Wm. McQuinn, superintendent of the Pacific mine, arrived in town from the Klannath on Thursday evening, and says he has commenced another cut with good success. The bedrock has not been reached yet, as a longer pump is needed, which he intends procuring. The Yreka Creek M. Co., since the cool weather, have secured a better supply of water, which allows about 11 inches of water to the elevator each day. About next Thursday or Friday the machine will be set down on the bedrock. The flume in which the gravel is thrown has been lengthened considerably, toward saving the gold. Bedrock may probably be found before the machine is moved, as it is higher on the east side than on the west side of the large pit, now being enlarged by the aid of the giants.

SIERRA.

BATA MOUNTAIN.—*Nevada Transcript*, Oct. 2: Six hundred tons of gravel from the Bata Mountain mine at Forest City are washed away weekly at present with water from the tunnel. The dirt pays \$4 per load. A party of ladies and gentlemen who went into the mine the other day had a thrilling experience. They had stopped a mile underground. At a point between where they stood and the mouth of the tunnel 23 cars loaded with gravel broke loose from the engine and started down grade toward daylight. After running a quarter of a mile a smash ensued, wrecking five cars. One man bravely ventured to stop the runaway train by running alongside the track and, in the darkness, putting on the brakes. He succeeded very well until he reached the fifteenth car, when unfortunately he made a misstep and received a fall, breaking his collar bone. It was several hours before the debris was made away, as the people in the mine could pass it and make their exit.

RICH RIVER.—*Mountain Messenger*, Oct. 2: It is said that a Chinese company, below Barabard's, have found a very rich spot in the river, and took out \$800 in one day.

NORTH FORK LEASES.—T. Marriott & Co. have leased the North Fork mine at Forest City, both gravel and quartz, for a term of two years. They have already struck better gravel than has been found for a long time, and will soon put on men and commence taking out pay dirt. The contractors are energetic and experienced miners, and we believe they have a good thing.

JAS. PATTERSON.—Of Excelsior hill, has bought out his partner, Jacob Kolb, and purchased nearly all the adjoining claims, thus making a fine mining property now.

BATA MOUNTAIN EXTENSION.—While over at Forest City early this week we were complimented by the accommodating contractors of the Bata Mountain extension with a ride through their air-line tunnel, 2300 ft in length, and around the bend 200 ft to the left and face, where 8 ft of a face is being made in rather soft bedrock. Walter Lawry, Denis Finane, Thos. Veale and Henry Fowler, the present contractors, assisted by Nicholas Frater and Oliver Hale—all old and experienced miners—are very confident of completing their thousand ft of tunnel by the 1st of next January, unless prevented from doing so by hard rock. A place is being graded for a timber house.

NEVADA.

WASHOE DISTRICT.

The following are from the weekly statements of the leading mines:

SAVAGE.—Have repaired and retimbered 13 ft of the main shaft and 0 ft of the 10th station, and then put the station force into the head of the incline, immediately under the station, to do some retimbering and repairing, in connection with the station work. Have driven the 10th-level drift 17 ft.

DECKARD.—Foundations for the pumping engine, etc., along the corner of the shaft to be used in hoisting at, all lowering pumping apparatus ready for use. Station at 2400 level for pumps is completed, and tank station there to supply the pumps is excavated. Commenced shipping machinery Saturday.

EXCELSIOR.—During a part of the preceding week we were engaged in timbering the north drift, 2510 level, in places to prevent its caving. The drift is now in 108 ft. The latter part of the week we were engaged in repairing the gallow frame (Imperial) and overhauling the blower engine on the surface.

CALDONIA.—The pumps have been run an average of 10 hours per day, consuming 7 1/2 tons of coal per day. The Furman shaft has been sunk and timbered 20 ft, total depth, 1,400 ft. The masons have finished setting the new boilers.

CON. IMPERIAL.—During the preceding week we have been repairing the gallow frame on the surface and overhauling the lower engine, so we have not been able to do any work in the mine proper.

GRANADA.—The pump foot is in place as far up as the 600 level, perpendicular shaft.

GODD & CURRY AND DEET & BRECHER SHAFT.—We have sunk during the week 25 ft; total depth, 1,665 ft.

EUREKA DISTRICT.

EUREKA TUNNEL.—*San Francisco*, Sept. 28: The Eureka tunnel is now in 1,457 ft, the face still being in shale. The shale belt has been penetrated 100 ft, and it is believed to be from 30 to 40 ft wider. When the west of this shale is reached, it is believed our will be encountered. The Superintendent is also prospecting for drifts in several places, everything being done in a thorough and systematic manner. The blacksmith shop and sheds which were burned by fire a few weeks since have been replaced by iron buildings, and other improvements made, all showing the confidence the projectors have in the future development to be made in Prospect mountain at depth; and every practical miner in the district believes it will prove to be the largest property upon the mountain, as it will also afford facilities for working many mines now lying dormant.

MOREY DISTRICT.

THE MINES.—*Belmont Courier*, Sept. 1: On the 200 level of the Magnolia ledge, one of the Morey Co.'s group of mines, is a 15-inch vein of argenteous fair ore assaying \$200 per ton. This strike is important. Hitherto the mines have been producing \$8,000 per month, but lately the shipments of bullion have doubled. From the present outlook and the new developments in the deepest workings of the Magnolia, one of the ledges owned by the Co. and the Kaiser, another ore-producing ledge from which high grade ore has been extracted near the surface, the camp never looked better, and promises to be a bullion producer for some time to come. As soon as the stopes are properly opened the mill will be run on full time. Every opportunity is offered visitors to examine the mines. The Morey mines several years ago were indifferently worked for some time, and with limited success. Lately they fell into the hands of the Bernheimers, bankers in New York City, the present owners and managers who are sojourning in the future as to make it a largely producing and dividend-paying property. Many improvements have yet to be made in the working of the mines looking in the future to their being systematically and profitably operated. Since the mines have been worked to a depth the ore greatly improves in quantity and quality.

WARD DISTRICT.

SMELTING ORE.—*Ward Reflector*, Sept. 28: Ore of a smelting character has been discovered in the Madre tunnel. We are informed by Robert Briggs, Superintendent, that will go as high as \$70 per ton. How large a body has been struck is not yet known. The tunnel is now in about 400 ft.

ARIZONA.

MINERAL CREEK DISTRICT.—*Silver Belt*, Oct. 25: Mr. Putnam, of Riverside, called on us last Tuesday, and was very enthusiastic about the prospects of the Mineral Creek project. The late copper finds there are astonishing. Mr. Boulanger is shipping ore which carries 40% of copper. There is a good road from Riverside to the mines, which are about 15 miles from the town. Putnam forms up the Boulanger is an old copper mining man, that he has visited the Lake Superior and Clifton countries, and has not seen anything at all comparable with this new copper region.

THE VERDE.—Messrs. House & Rouse, of Tonto basin, report that in their camp everything is quiet, but that on the River Verde times were lively. Their mine, which we are assured is the best in the border of Sonora, is rich in copper. They have 150 tons of good ore on the dump, and the mine is looking well. They tell us, that on the East Verde the miners have taken out a ditch to carry water to arastras, by which process they intend for the present to work their ores. The mines along the Verde are gold mines.

GOLD DISTRICT.—Messrs. Thornton, Hogarty & Winber, made a discovery about two weeks ago, which consists of a vein 5 ft wide carrying mineral its entire width. The mine is known as the California. Work has been commenced on this La Plata, and we now look for some good returns from that property. Mr. Edward Ayers who has been for some time night foreman at the Silver Nugget mine, but not in the employ of the company at present, tells us that the mine is in excellent condition, and says that it is one of the best mines he has ever seen. He says that the whole country is seamed with veins, and that the best developed of the mines are only hinting at what lies beneath. Agnacio Campbell is smeltering copper, 4 miles south of town. A 1,000 lbs. lot of copper, also carrying gold and silver, 95 fine, can be seen at S. Klein & Co.'s store. It will be shipped to San Francisco for separation, with a view of ascertaining whether or not it will carry gold. An old friend Capt. Tucker has, through his untiring perseverance, blown the whistle of the Townsend mill, and are long we shall expect to take a good look at his gold bullion. The pump for the Nugget mill has been received and is now being put in place. The Clipper, belonging to Chas. Prather, is revealing rich ore which fills the bottom of the shaft.

BULLHEAD.—*Arizona Citizen*, Sept. 23: The Tombstone mill and mining company shipped from Millville during the past week bullion valued at \$22,038.04.

THE ALTA.—As work progresses on the Alta mine at Harshaw, of which Hon. J. K. Luttrell is manager, it begins to be demonstrated that it is one of our coming bonanzas. Word reached Tucson this morning that at a depth of 100 ft the mine is in a large body of rich ore, and the following assays are given: \$270.00, \$335.40 and \$332.55.

BIG PRODUCTION.—The Copper Queen smelter at Bisbee, in the Mule mountains, is a bonanza, and no mistake. It produces copper bullion at the rate of 700 lbs per hour, or 17,500 lbs per day, or 504,000 lbs per month—252 tons. This copper, at the latest quotations, is worth \$100 per ton, and the cost of getting it to market is 25 cents per lb, leaving the value of the mine's production, in round figures, \$93,000.

IMPORTANT STRIKE AT SAN XAVIER.—The mines of the San Xavier mining and smelting company are of great importance to Tucson, as they are the nearest to the city of all our productive mineral properties. It is, therefore, with pleasure we record a new strike in the western extension of the San Xavier mine. The locality of the rich find is in chamber No. 1, on the south crosscut on the 100 level, and consists of the whole face of the chamber being in a very large body of galena ore, assaying 76% lead and 70 oz of silver to the ton. The extent of the body is of course not yet known, but the indications are that it is very large. This property is rapidly being taken to the front as a very rich property, and its successful operation will prove of immense benefit to Tucson. The new smelter is at work, though it will be some time before the production of bullion will be as steady as when experience has taught all the particulars for working the ore to the best advantage.

COLORADO.

ERIE SMELTER.—*Georgetown Courier*, Oct. 3: The Erie smelter company at Junction have commenced hauling ore from the Smith & Oray mine, having purchased 50 tons as a sample. There are now over 100 tons of ore on the dump. The four great mines of Custer county, the Bassick, the Bull-Domingo, the Silver Cliff and the Plata Verde, have given employment to 500 men for several months. A smelter is building at Arboville and good prospects for another at Junction and Garfield City. Buenos Vista will have a smelter and sampler before the end of the season. The Mt. Shavano smelter, at Mayville, made a successful run last week, reducing in 5 days all the lead

ores on hand and producing 5 tons of bullion, valued at \$2,000, besides shipping 4,000 ounces of dry ore. The smelter at that place has given a fresh impetus to mining matters on Battle and Horn Silver mountains. The Union mine on Mineral hill, at Breckenridge, has been sold for \$50,000. Eastern parties were the purchasers.

CAIRNDALE LODGE.—*Register-Call*, Oct. 1: The Italians who discovered and have been working this silver-bearing vein at the mouth of the left-hand fork of Missouri gulch, are now down to a depth of 110 ft. A drift east, at the depth of 100 ft, has been driven 30 ft, and a vein of mineral averaging 4 inches has been uncovered. Messrs. Locke Bros. & Hunderman, while not working as strong a force of miners as formerly in the Hlad Money lode, have good ore bodies at different points in the mine. Col. Smith, agent of the Silver King mining company, has struck into a rich body of ore in the Alaska mine. The crevice is unusually rich for a silver vein, and is quite rich in silver and lead. Prof. S. W. Tyler, agent for Eastern parties, has let a contract for sinking the main shaft on the Return lode. A new whim has been erected to facilitate hoisting the material mined.

THE BOSS LODGE.—Messrs. Sayr & Owen have been proving up the extreme easterly portion of the Boss. A tunnel shaft vein has been struck at a depth of 100 ft, which will be driven until it intercepts the deep gr main shaft.

IDAHO.

RAY HORSE.—*Cor. Yankee Fork Herald*, Oct. 2: At Bay Horse, 10 miles from Oballs, we found the smelter all set for running and waiting only for a supply of charcoal. In the bins were 700 tons of ore to start with and more coming down from the mines. There are 15 or more mines sending ore to the reduction works at the Ramshorn. Hood, Beardsley, Fults, O. K. Excelsior (Ute Boy, Bull of the Woods, Silver Wing, Skylark, Keystone, Little Fellow, Cabin and some others. The Rob Roy and Centennial are also getting out ore. The Ramshorn Co. has contracted to deliver 300 tons of first-class ore as fast as it can be got out; the Faithful Boy 100 tons, and the Beardsley is furnishing 20 tons per day of ore that runs high in lead and low in silver, and carries the base of the reduction of the high grade ore. A number of the mines mentioned are on what is known as the Ramshorn vein—the longest continuous quartz lode known to the mining world. There are 29 1500-ft locations on it, and ore found on every one of them, making it all of 5 miles in length. The smelter is a most perfect piece of work for reducing base ores, and has been erected under the immediate supervision of experienced smelting men. The organization is known as the Bay Horse mining and smelting company of Omaha. E. W. Nash is Secretary and Treasurer, A. J. Crook, General Manager and Smelter and Geo. B. Moulton is the mining expert of the company. Jas. A. McNab, of the Ramshorn, attends to the sampling of the ores from the various mines. The smelter is about 30 tons capacity, is favorably located on Bay Horse creek and in a very fertile and high grade silver belt. The establishment of the Bay Horse reduction works has put new life into that portion of our mineral field, and the long looked for boom has sent the Bay Horse off on a gallop and brought joy to the heart of many an honest miner.

KINNICKINIC DISTRICT.—Leaving the Bay Horse works we took the trail over a distance of 15 or 16 miles, to Kinnickinick. We found another field of active mining operations. Where two months ago there was not even a decent trail, we now find a brisk camp, good wagon roads, safe and easy means of transporting goods and machinery, and smelting works fast approaching completion. The company operating at Clayton, mouth of Kinnickinick, is known as the Salmon River mining and smelting company of Omaha. The president, W. W. Lowe, General Manager and Treasurer, and W. L. Cusland, Superintendent. The well developed mines in the vicinity of the works are numerous. The ores are both abundant and rich, and the company owns some valuable properties. A good wagon road has been made down a tributary of East Fork to the main stream, thence down 6 miles to Crystal, mouth of East Fork. From there the road runs 2 1/2 miles to the south of the mouth of the Salmon, where the stream is being substantially bridged. From the bridge it is 1 1/2 miles up to the reduction works, where quite a brisk town is springing up.

EAST FORK.—From Crystal to the mines on head of East Fork is 38 to 40 miles. The trail is a moderately good one. The valley of the East Fork is from 1 to 1 1/2 miles in width, and covered with heavy timber. Along the bottom of the valley the company has about 25 locations, most of them on the rim of a basin at the head of a small creek 2 miles long and on the north side of the North Fork. The ores are galena, carbonates and free milling. The highest grades of ore from which assays have been had, give from 300 to over 700 ounces silver per ton. We visited some of the principal locations, and found them to contain strong veins of fine silver ore. Among the most prominent veins are the Germania, Old Bible, Cal, Cresson, Full Hand, Karnace, Alta, Idaho, Sanderberg, Arctic, Warsaw, Silver Shield, Top, Silver Bell, Deseret, Washington, Yellow Jacket, Olden Wonder, Sperling, etc. Several tons of shipping ore are out at the Idaho, and the owners of the Germania have 10 tons of ore sacked for shipment to the Bay Horse smelter. It is clear galena and assays from 100 to 300 ounces silver per ton.

MONTANA.

ARGENTA.—*Butte Miner*, Sept. 30: Argenta, the pioneer camp of the Territory, is looking very favorable just now, with a good show for the future. This camp has for several years been partially abandoned, but there is much good smelting ore in the district, some of which will be worked within a year. Mr. Smith Ball, operating the Tootle & Hanna furnace, is doing well. He has a large miscellaneous lot of galena ore (120 tons) which yielded \$10,077 in gold, silver and lead. The furnace last week finished a run of 80 tons of ore which produced 18 tons of base bullion of good grade. The furnace is now running on Bully, Legal Tender and other ores of the district that will result well. Some of the mines in the Argenta district are looking fine, exposing splendid bodies of galena and carbonate ores, carrying both gold and silver in paying quantities.

CON. BRAY & SON.—Have a new opening on the Legal Tender of 4 to 5 ft of high-grade galena ore. Life Scott has his Bully lode surface opened for a distance of 200 ft. The vein is 3 to 4 ft thick from top to bottom, sampling 40% to 50% in lead, 60 to 80 oz in silver and \$3 to \$11 in gold to the ton. The old Tootle & Hanna lode Messrs. Tootle & Hanna have just commenced operations. In the Argenta district quite a number of mines will be worked from now on—among them Life Scott's Tootle & Hanna and Tilden, the Paymaster, Stapleton, Fletcher's Gov. Tilden. There is enough good quartz prospected to run the Tootle & Hanna and the Seligman furnaces all next season. The ore will be mined the coming winter, and the old Argenta camp will be running two furnaces next season.

ALICK.—The stopes, though wide, are all in ore, no attempt being made to extract the full width of the vein. Crosscutting from the 700-ft station has not yet been resumed, as the discharge pipe has not yet arrived.

ORAY ROCK.—Operations in the new shaft, which got to be too deep for the successful working of the whim, are still suspended, awaiting the arrival of the necessary steam-hoisting machinery, which is expected in a few days.

GAGNON.—The first-class ore is being shipped East for reduction, and the second class is treated at the Colorado works. The present machinery is thought to have power sufficient to sink to a depth of between 400 and 500 ft.

COLUSA.—The new shaft is making excellent progress, and is now down 110 ft. It will probably pass through the vein within the next 50 ft, after which a rather heavy volume of water may be expected. The hoisting gear for this shaft will be the largest in the Territory.

STAR WEST.—The two shafts, at a depth of 100 ft, have been connected by a drift, which shows a continuous vein of high-grade ore from one to the other. It varies from 2 to 3 ft in thickness, and possesses an average assay value of \$200.

BUTTE NEWS.—Another huge mining enterprise is on the tapis in Butte. A new strike of rich ore is reported on a claim near the Centennial mill. The Rocker mill has been

purchased by Mr. Robert McMillin, and will be remodelled. The concentrating works, lately fitted up by Bosrdman & Sons, some distance south of the copper smelter, have been started up with very encouraging prospects of success. The daily capacity is 15 tons, and the first run is being made on Parrot ore. There is no camp in the world which can boast of so many paying mines and so few non-paying ones as Butte. The air tramway connecting the Colusa mine with the smelter has been finished for the first 500 ft. Its highest point will be 60 ft. The bulk of the hoisting machinery for the new Lexington shaft is being manufactured in Butte. The Silver Bow mill is putting through a 100-ton lot of Pacific ore. If the run proves satisfactory, the Pacific will be opened up with a big force. It is one of the largest veins of the camp. The Alice company yesterday shipped 5 bars of bullion valued at \$10,000. The 200-ton ore dump of the Pacific mine is being shipped to Silver Bow mill. It is stated on good authority that the southern portion of the Crow Indian reservation will shortly be restored to the public domain, in order that the Clark's Fork mines may be located and developed. The Crows will interpose no objection.

NEW MEXICO.

NEW MEX.—*Herald and Southwest*, Sept. 25: The 10-stamp mill at the Massachusetts and New Mexico mining company started up in earnest last Monday, and during the week, crushing ore at the rate of about 10 tons per day. All the machinery works smoothly. The ore, as taken from the bins, is first passed through a No. 3 Dodge crusher, which reduces it to a suitable fineness for the Challenge self-feeders, through which it passes to the battery. The stamps are run at the rate of 90 drops a minute, and have a crushing capacity of 10 tons of ore per day. Through a 50 mesh wire screen, the pulp passes into 7 tanks, and from the lowest of these the surplus water runs into a reservoir below, whence it is pumped up to be again used in the battery. It is claimed that by repeated use of this water, the chlorides and other refractory elements are brought to a condition in which they can be readily amalgamated. Below the tanks are 4 elevating screw amalgamating pans, which play a joint capacity of 20 tons per day. Still lower are 2 Wheeler & Randall's rollers, 1 Agitator and 1 True concentrator. The mill is run by an engine of 145-horse power, although at present only about one-third of this power is used. The company has about 1,100 tons of ore on hand, assorted and ready for the mill. In addition there are nearly a hundred tons stored in the shafts and drifts of the mines, besides large quantities in the various dump piles now being assorted. There are no less than 9 points on the Legal Tender where men can be put to work and ore taken out in large quantities. The assay office and laboratory are undoubtedly the most complete in the Territory, and the retort and refining room are fitted with everything required for thorough work. A clean-up will be made early in the week, and this company will soon be adding regular shipments of bullion to the product of Grant county.

NOTHING YET.—*News and Press*, Sept. 30: The Diamond Drill company have already penetrated 200 ft into the side of the mountain at Poul Park, and although the core shows that they have crossed several small veins of mineral, they have not yet struck any that they desire to develop.

OREGON.

QUARTZ AND PLACERS.—*Redrock Democrat*, Sept. 26: The mining, both quartz and placer, throughout our country for the past season has been of the most satisfactory results. Without doubt, instead of diminishing, the mining industry in this section is greatly on the increase. Hardly a day passes that we do not have to chronicle new discoveries, and of the very richest class. Rich silver ore has been discovered lately near the mouth of the New England and Oregon mining company at Rye. The mine has struck it rich in the Oreen discovery. The vein is good sized; some of the samples assaying \$10,000 per ton. Powers & Co., of Rye Valley, are still mining their hydraulic claims. They will clean up for this season some \$25,000. The Connor Creek mining and milling company keep their 2-stamp mill running night and day on the rich Oreen discovery. The mine is a very rich one, and the Monumental mine and mill will start up this week, with expectations of a large output. They have a rich ledge. The new mill recently erected on the Tom Payne ledge (Hayes & Co., near Peachontas, is turning out large amounts of bullion daily. Placer miners generally have done well throughout the county, and their clean-ups very satisfactory. Last week \$10,000 in dust was sold at the Butte & East Fork assay office. W. W. Wilson, of Mt. Fort is up in the Orianite Creek mountains with a large gang of Chinamen building a ditch to carry water on some very rich gravel claims. The Sutton Creek quartz excitement remains unabated. Large pieces of gold, mixed with a little quartz, are being found daily. Joe Lee & Co. recently cleaned up \$3,000 from their Clark's creek claims.

CLARK'S CREEK.—James Noris, Kidd & Tatro made a very rich clean-up from their placer claims last week. Several persons, working what is known as the Bar claims, are realizing splendid results. They have a "Little Olan" hydraulic at work on these claims, and working out considerable ground. Everyone in this burg seems to be happy and contented. Two different mines have turned out well for the past season, with a brighter future in store.

UTAH.

ALTA DISTRICT.—*Salt Lake Tribune*, Oct. 2: The Eclipse mine is a separate property from the Flagstaff, and all of the portions of the former mine that the latter has patented. The Emma is looking well for the depth zone. The incline shaft is now down about 150 ft below the level of the Bay City tunnel. The rock now worked in indicates the near approach to mineral. The workings of this company are not made public. Of the Silver Bell sale there is nothing new reported, although rumor had it that the sale had been accomplished during the week.

PINE GROVE DISTRICT.—From Mr. C. W. West we learn that the mines of Pine Grove district are looking well. The property of the Consolidated company develops well. The shaft on the Carrie Lucille is down 90 ft, and samples from the ledge assay 300 lead, 176 oz silver and \$15.07 gold per ton. The ore is about 100 tons of ore on the dump that averages as quoted above, and the company is now making arrangements to ship either to Milford or Frisco. The ledge averages 5 ft in width. The Hidden Treasure has 18 inches of very fine carbonate. This claim is north of the Carrie. A new vein has been struck inside the Miller lines which is said to be far superior, in extent and quality, to the original ledge on which the discovery was made. There are now only 12 miners at work on the claim, besides a few prospectors. Pine Grove district is situated about 25 miles southwest of Frisco, and over the range from Waw-Waw Springs. The country is well watered, and timber is abundant, as the name of the district would indicate.

PARK CITY MINES.—The bullion shipments from the Ontario mine the week ending the 24th amounted to \$347,200. The surface water tunnel at the Hawkeye is about completed, and sinking will be resumed next week. Soon there will be 3 steam whistles in McHenry gulch, where for 8 years prospecting has been carried out without a pound of machinery. The new salt batteries at the Ontario mill are working very successfully. It makes a difference in the amount of ore crushed of 10 to 12 tons every 24 hours. Drifting in the Olencoe started up again on Wednesday morning. There is between 40 and 50 tons of ore on the dump which will average 50 oz silver and 40% lead. The mines are all getting in their winter supplies. Wood, for fuel, is one of the necessities that is getting scarce, which will be supplied without stint when the railroads reach us. There are vast forests along the Weber river from which the wood can be floated down to the depot at Wanship.

The product of the Idaho mine for the month of September was \$40,000. The usual monthly dividend of \$5 per share, amounted to \$15,500 has been declared.

Silver Cliff's Mines and Mills.

A correspondent of the N. Y. *Tribune* writes as follows from Silver Cliff, Colorado: The future of this city is now assured, and strangers not conversant with mining camps can hardly believe that on the present site of this hustling city but two years ago roamed herds of cattle, and the howl of the wolf and coyote was the only sound that broke the stillness of the midnight air, where now are heard the blast of the miner and the pounding of our mill stamps. Our mines are constantly growing in value as developments progress, and ores are found rich in chlorides where no experienced miner would ever think of prospecting. In fact, our camp is an anomaly and breaks down all established precedents in finding ore rich in gold, silver, copper and lead.

The Racine Boy mine, the first discovery in our camp, has been steadily worked for two years, and to-day shows richer in ore and more extensive in deposits than was anticipated by the most sanguine of its owners. Openings are now being made on the face of the cliff in the adjoining properties, and all show one general formation of deposit, carrying chlorides in greater or less quantities. The Racine Boy mill of 40 stamps has not been a perfect success; nevertheless, when it has been in repair, it has steadily produced near 1,000 lbs. of bullion per day of 24 hours and this from 35 tons of ore, giving an average of near \$50 per ton.

Ground is now being broke to erect a mill of 60 stamps. This mill is to be of wet process, and it is predicted will crush 150 tons per day of 24 hours. Should this prediction be fulfilled it will show a production of bullion of at least \$4,000 per day, and this company have ore enough in sight and prospected for to last a generation.

Extending north and west from this company's mines are hundreds of mining claims that indicate the same general formation, and there is no question but that in the near future, with milling facilities, thousands of tons of ore can be produced that will pay liberally over both the labor and milling expense required in transforming the ore into bullion.

I shall not attempt to enumerate the large number of mines that are idle for the want of milling facilities, but can say without fear of contradiction that at least 1,500 tons of ore could be produced daily had we the milling facilities to treat the ore at a fair profit—the estimates being from \$4.50 to \$6 per ton.

I find it impossible to particularize in the large number of new discoveries that have been made in the past few months. Most of them have upon development increased in richness, and consequently in value, and Silver Cliff's future as a mining center has no equal when capital will find its profit in giving us the facilities to reduce our ores to bullion.

Grand View Mining District.

The Esmeralda *Herald* says: On the 17th of last month a meeting of the miners of a portion of what has heretofore been known as Mount Grant mining district, and those of the eastern slope of the Mount Grant range of mountains, bordering on the southwest portion of Walker lake, was called for the purpose of taking into consideration the propriety of forming a new mining district, the election of a Recorder, etc.

At the meeting A. G. Nowles was elected Chairman, and W. A. Virden Secretary. By a unanimous vote of those present, it was decided to name the new district Grand View. Its boundaries were fixed as follows:

Commencing at the mouth of Wildcat canyon, at the eastern base of the Mount Grant range of mountains on the southwest side of Walker lake, in Esmeralda county, and running thence four miles in an easterly direction to Walker lake; thence five miles along the western shore of Walker lake in a northerly direction; thence through the Blanchard pass in nearly a due west course to a point one mile below Buchanan's camp, on Cottonwood creek; thence two miles in a westerly direction to the summit of the range of mountains on the west side of Cottonwood creek; thence along the summit of the high range of mountains, on the west side of Cottonwood creek and Lapham's camp, to the high peak of mountain nearly north, and about one and a half miles distant from Wm. Barne's ranch and camp; thence across the south end of the Compton meadows to head of Wildcat creek; thence along the head of said creek to the place of beginning.

ANOTHER MINING DISCOVERY.—Some weeks ago an old prospector discovered a large and well-defined ledge of silver and gold-bearing quartz, in a porphyry country, on the high divide between East Walker river and the Sweetwater, about 35 miles west of Bodie, and since the discovery considerable work has been done upon the ledge, proving it to be of great value. The assays run up from \$15 to \$117 the ton, while some selected samples of the ore submitted to a fire test in a forge, gave out numerous globules of silver. Only six or eight locations have yet been made, and the exact locality of the new find is known to but few. The facilities for working are of the best, wood and water being abundant just below the mines, while the topography of the mountain on which they are situated is such that the ledge can be tapped at great depth by shafts.

The Comstock.

This body of ore just cut on the 2000 level of the Ophir, though not strictly speaking a new discovery, promises to prove very important of itself, and may lead really to a first-class deposit. They now have from ten to twelve feet of good milling ore. This alone, anywhere outside of the Comstock, would be thought a very good mine. Even though the vein should be found to grow no wider, a great deal of money can be taken out of it. As it is wider than where cut in the California, the vein is doubtless increasing in strength to the northward. In drifting along in that direction a large deposit is liable to be found. Also, there is room between the 2000 and 2500 levels for a first-class bonanza.

The work that has thus far been done on the 2500 level is too far to the east to strike the deposit. Whether or not the upraise will cut it remains to be seen. To follow the ore north and south, up and down, through all its ramifications, will be the work of some months. In doing this work, however, ore will be coming out right along.

Mr. Mackay says he has the most implicit faith in the Comstock showing good bonanzas of ore at the greatest depths we shall be able ever to attain. His idea is that in all those sections of the vein that have proved fertile, will again be produced bonanzas at some point below. He says: "Although we may not get these bonanzas in the next five years, still they will be found."

By this he did not mean to say that it would be five years before bonanzas would be found in the places where ore is now beginning to make its appearance, but that along the lode in all fertile sections bonanzas will again be developed, though it might yet be five years or more before they would be hit upon.

His reason for so believing is that the ore found at the greatest depths yet attained, is as clean, free and pure as it was above—that it does not run to iron, lead and other base metals. Also at great depths the quartz is as bright and the material of the vein as full of life as any point above. The principal trouble just now is that at most points there is too great a width of this vein material.

During his recent trip to San Francisco, Mr. Mackay had a conversation with Clarence King in regard to the probability of ore being found at great depths in the Comstock. He found Mr. King's views coincided with his own in every respect. As regards water in the direction of the Yellow Jacket, and at other points where considerable quantities of water are now making their appearance, he does not think there will be more than may be handled with any great trouble. Indeed, he takes a very hopeful view of the situation along the whole course of the vein, believing that in the future as in the past there will always be some point along the great mineral channel from which ore will be seen coming out.—*Virginia Enterprise*.

Silver Cliff.

The Silver Cliff *Prospect* says: It is tonnage that makes mining camps permanently prosperous. This single fact which should be patent to all is an important factor to be considered by capitalists desirous of engaging in, and legitimizing, the production of silver ores and the elimination of their values.

Ore veins so concentrated by nature as to be extremely rich, oftentimes enrich their owners, regardless of comparative inaccessibility, the necessity of transportation by primitive methods to and from points remote from the mines and notwithstanding climatic influences which render transportation and continuous working throughout the year an impossibility. The tendency to search for short roads to wealth is common to all men, and to many it is irresistible.

With the latter class, it is useless to argue that the shortest roads—or those which look to be so—are not always the surest or easiest.

They will continue their efforts to scale impassible mountains and penetrate impenetrable canyons, to live, devoid of home comforts—in cabins unadorned by the graces of civilized society until they lose—or forget—the refinements of life in the vain search for refined gold and silver, which, if found, would not be worth the sacrifices made to obtain them. It is not, however, the purpose of this article to point out and moralize upon what we deem the weaknesses of men who are probably strong where we ourselves are weak, but rather to state as clearly as possible, some reasons which have occurred to us for believing that Silver Cliff will be a prosperous commercial and bullion producing center when numerous other camps now claiming public attention, the mines of which are located midway between timber line and the eyerows of the "Man in the Moon," will have become reminiscences. Here where outdoor work is practicable every day in the year, where every mine is accessible by fine natural roads, with a large area of arable land, the products of which are a continual check upon the market for food supplies, capital and labor, brain and muscle can and must work together in the production of nature's economic wealth.

It is not the accumulation of vast wealth in the hands of a few, but its production and diffusion among the many that works the greatest good to the greatest number and builds up and peoples populous cities and States.

Mine products so compact and rich as to bear

help to swell the wealth of communities where such mills are located, while the mines in most cases remain for an indefinite period surrounded by comfortless cabins and "dug outs," which are in time deserted by men and become the habitations of owls.

But on the other hand in a region where ore bodies are vast in extent, and their values so diffused throughout the whole mass that they can only be eliminated successfully and profitably with the aid of expensive machinery, the result is widely different.

Once established that such ores can be mined and converted into bullion at a cost which will leave a large percentage of profit when done upon a large scale at the mines, money which fails of profitable employment elsewhere, will be used in the construction of mills. Labor will find remunerative employment, and 50% or 75% of the bullion product—in money—will flow into the channels of trade around and among the homes occupied by the workers and their families.

The continued healthy growth of Silver Cliff is a signal illustration of the happy results which spring from the harmonious working of labor and capital in the development of mines and the treatment of low grade ores.

A little more than one year ago, we had no machinery, and but one mine that was producing ore, in quantity, sufficiently rich to leave a margin over working expenses, after deducting the cost of wagon and rail transportation, with cost of treatment elsewhere. Very few believed then in the permanence of our camp; but now all is changed. The introduction of machinery at an aggregate cost, in cash, of \$1,000,000, which yields a large revenue to the owners so long as it is in motion—but would deteriorate rapidly if allowed to be idle—has wrought a magical change in this camp by creating a feeling of confidence in its future, which is drawing hither additional capital to be wielded by representative men of the more enterprising class from every Eastern State.

The four great mines of the camp now prepared to treat their output, the Bassick, the Bull-Domingo, the Silver Cliff, and the Plata Verde, have given employment to 500 men for several months.

The wages of these men and the supplies purchased here by the companies, sum up about \$90,000 a month, and with all their machinery in active use, as it will be soon, these several companies will add more than \$400,000 a month to our bullion product.

This fact demonstrated as it will be this season, if the management avoid the unwise policy adopted by Leadville organizations, of exhausting their reserves in order to pay large monthly dividends, the mine now here will form a nucleus around which will spring up millions of dollars worth of machinery next year and the year after, giving employment to thousands of men, who will use their money in building and beautifying homes here in the picturesque Wet Mountain valley.

With an inexhaustible ore supply yielding thousands of tons daily, all of which will be reduced to bars of silver and bullion here, the truth of the sentence at the head of this article will be apparent at home and abroad, and our predictions, farther on, as to the future prosperity of Silver Cliff, will be in the way of verification.

SAN XAVIER.—J. Andrews, who has charge of the work on the San Xavier mining company's property, came in from the mine last night, and from him we learn that the company's new smelter was started up on the 1st, and worked to the complete satisfaction of all concerned. It was run a day or two and then shut down to finally complete the arrangements, and to remedy such trifling defects as the experimental run disclosed. In a few days everything will be in order, and then the smelter will set out on a cruise which everyone hopes will be extremely profitable to the owners of the mine. It is a 30-ton furnace, and is located about eight miles from the mine, from which the ore is hauled by wagon. About 1,000 tons are now lying at the furnace, and the teams are at present hauling about 25 tons daily, which amount can be increased whenever necessary. The mine itself is looking splendidly. The two working shafts are now down 120 ft. each, the bottom in 30 ft. wide of fine black ore, which, however, is hard enough to require roasting before it will melt freely. This ore, at a low estimate, carries \$40 per ton in silver, and from 35% to 40% in lead. The diamond drill owned by the company—the only one in the Territory—is doing good work. A core was taken out in one direction for a distance of 250 ft., and it disclosed several fine-looking bodies of ore. It is now headed in another direction. The economy of this method of prospecting a mine is being rapidly made apparent by the work which the San Xavier company are doing.—*Arizona Citizen*.

MESSRS. GODBE, HAMPTON & BIGELOW have purchased the American Flag mill of 20 stamps at Pioche, Nev., and will begin the work of crushing ore. They have also purchased the tailings of the Raymond & Ely mine, which they propose smelting into bullion as soon as the parties can erect smelting works. Mr. Hampton, who has been in Pioche in the interest of the company, left here for Salt Lake Thursday, for the purpose of shipping the machinery, etc., necessary to put up a smelter.

WISEMAN & Co. have leased the South Yuha Water & Mining Co.'s hydraulic mine at Quaker Hill, and will work it this season. John Noyes

Richmond Basin.

This camp is located on an elevated plateau on the west slope of the Apache mountains, a little east of north from Globe, and distant about twelve miles. It is nine miles from the Basin, north, to the nearest point on Salt river where water is plentiful. The summit of the Apache mountains is covered with a growth of pinon, juniper, and other woods, suitable for fuel for steam, coal, etc., and the nearest accessible timber available for mining purposes is found in the Sierra Anchas mountains, distant northwest 20 miles. Two good roads lead to Globe, via Wheatfields and Silver Nugget mill.

What is claimed to be the mother lode is located for 1½ miles, the ledge cropping out boldly the entire length. The West and East Richmond, Mack Morris, La Plata, and Defiance are the principal locations on this vein, the lead coursing east and west, and dipping to the north at an angle of 7° 10'. The width of ledge varies from seven to fifteen ft. at the surface, and increases as depth is attained. The ores are chlorides and sulphurets, the former being found near the surface, and native silver at the water level.

The first location made here was the West Richmond, Feb., 1876. It is now owned by M. A. Baldwin & Co., and a small force, soon to be increased, is at work. One hundred tons of ore have been taken out since purchase, by present company averaging \$100. The greatest depth on lead is 90 ft. There are also two drifts in smaller shafts.

The East Richmond has a shaft 45 ft. with a drift running east on the vein, 65 ft., all in ore of high grade, an average sample of the rock worked in San Francisco going over 400 ozs. The property belongs to Wilder, Riebridge & Co.

The Mack Morris is an incorporated company, stock not listed. The main working shaft is down 200 ft., and cross-cuts at the 100 and 200-ft. levels are now being run. The winze is down on the vein, east of working shaft, 175 ft., showing five ft. of ore which will pulp from 250 to 400 ozs; character of ore, sulphurets and bromides. There are steam hoisting works on the mine.

The La Plata (just sold) adjoins the Mack Morris on the east. At a depth of 82 ft. in the main shaft, water was struck and work suspended for want of proper hoisting apparatus. Good ore is shown here of same general character as in Mack Morris.

The Defiance shows no developments except assessment work. It is owned by Watson & Saunders, formerly of the Silver Era Co.

The accidental breakage of a force pump for the hoiler has caused a temporary suspension in work on the Silver Nugget and a consequent slight delay in the shipment of bullion. A pump has been ordered by telegraph, and is now in transit. In the meantime, one has been borrowed which will be working by next week. The working shaft on this property is down 145 ft. in good ore, with stopes, cross-cuts and levels. At a depth of 130 ft. a well-defined vertical ledge is found, two ft. in width, of very rich ore.

There are many other properties which we did not have time to visit, on which more or less work has been done, among which are the South La Plata, Silver Gulch, Marengo, Gift, Last Chance, Great Eastern, Rifleman, South Silver Nugget, Ocher, Blue Gap, North Richmond, Friday, Helen, Montague and Cora, the latter belonging to G. W. Sharp, and said to be a remarkably promising claim, and now worked for a large sum.

It is prophesied by old residents here, who have shown their faith in the camp by staying with it for years, that this will be the bullion producing section of Globe district.—*Globe Chronicle*.

NEW MINING DISTRICT DISCOVERED.—Some two months ago a small party of prospectors, headed by C. Beck, Esq., started for the Summit region to prospect. The Summit is 65½ miles, and 7,832 ft. above Sonora, a granite country. We have seen specimens of two locations—the "Unknown" and the "Lost Quartz." The "Unknown" was discovered on the 6th, near the Summit, and has been in eight for years, and needed but an experienced eye for conditions and a knowledge of ores to bring it to light. It is on trap belt—of which is the foot-wall; and the hanging wall is supposed to be slate, as judged by the float. The width of the vein is not known—although 10 ft. of vein has been found, with 8-inch gouge on foot-wall. This ore will go about \$300. The "Lost Quartz" is about 3 miles from the above location, 1,000 ft. wide in stratifications, contains silver and lead, and will go about \$150 per ton. Mr. Beck resides in Tolueme—is a graduate of Frieherg, with practical experience in the mines of Hartz mountains. He has confidence that a first-class mining district is located there, and it is the intention to build substantial cabins for winter quarters, and demonstrate its extent by practical work.—*Tuolumne Independent*.

STAR DISTRICT, Utah, is attracting the attention of experts and capitalists. The former invariably report favorably upon the district and the mines, most of which show well, so far as developed. The *Tribune* looks for an unprecedentedly large mining boom in Star district in the future. Aside from the richness of its mines, the juxtaposition of the district to the railroad

THE ENGINEER.

Railroads in New Mexico.

American enterprise seems to have taken hold of the work of providing Mexico with railroads at this right end. The only road of any consequence now operated in Mexico is the line from Vera Cruz to the capital. Of those projected, the most important are probably the Sonora and the Mexican Central. These corporations are organized under the State law of Massachusetts, and are controlled in the interest of the Atchison, Topeka and Santa Fe road. The Sonora road is to meet this line on the Arizona frontier. It represents a subscribed capital of \$1,200,000. The Mexican Central is to connect El Paso to the capital, with branches to the west coast and to Laredo. Work on these lines is pushing rapidly forward, and the material aid which has been extended to them in the shape of land grants and mileage subsidies is said to be sufficient to insure the financial success of the undertakings. A line competing with the Mexican Central has been projected by the Southern Pacific interest, and the San Antonio and Mexican Border Company have another in hand from San Antonio to Laredo. This is important, as it will connect the Rio Grande with the California coast and the railroad system of the United States. Several other roads have been surveyed, and within two or three years we may expect to see a great change wrought in the crippled and impoverished republic south of us. The extension of railroad facilities, the development of commerce, and the introduction of Northern enterprise and capital will lend the thrill of a new life through the Mexican nation. Commerce is the most potent of civilizing agents, and when the work of the railroads is accomplished Mexico will have a stable government and whatever else contributes to the prosperity of a people and the permanence of their institutions. It would seem as if the risk incurred by capital at the outset was great, but there can be no doubt that the work now in hand will ultimately accomplish great good and yield large returns. —*Iron Age*.

THE CAPE COD SHIP CANAL.—A joint committee of the Massachusetts Legislature was appointed early in the spring of 1860 to consider the project of cutting through the Isthmus of Cape Cod, for the purpose of navigation, connecting Buzzard bay with Barnstable bay by a ship canal. The matter was reported favorably, but nothing was done until the last few months, when A. G. Fisher a commission merchant and ship broker, of Boston, became interested in the scheme, and found little difficulty in enlisting New York capital. A company was formed, and \$8,000,000 of capital subscribed, of which sum \$1,500,000 has already been paid in. The contract for building the canal has been given to Adam Driehach and John Cameron, of New Jersey. The proposed route of the canal has already been surveyed and fixed by the engineer in chief, George H. Titcomb. The new company has secured a strip of land 1,000 ft. in width along the whole distance through which the canal is to run. The starting point of the canal will be near the little village of Sandwich, and it is expected that 2,000 men will be put to work immediately. The canal will be $7\frac{1}{2}$ miles long. It will shorten the route between New York and Boston 90 miles, and will secure an in shore route between these cities practicable for such passenger and freight boats as now ply on Long Island sound. It is estimated that there is an average annual loss of 6,000 tons of vessel property, and from 30 to 40 lives caused by ship wrecks, occurring around Cape Cod. The canal will be 141 ft. wide at the top, and 6 ft. wide at the bottom. It will have an average depth of 30 ft.

SAW-MILLS.—The art of preparing timber has been greatly simplified in modern times. The old practice in making boards, was to split up the log with wedges, and, inconvenient as the practice was, it was no easy matter to persuade the world that the thing could be done in any better way. Saw-mills were first used in Europe in the fifteenth century, but so lately as 1555, an English ambassador, having seen a saw-mill in France, thought it a novelty which deserved particular description. It is amusing to note how the aversion of labor-saving machinery has always agitated England. The first saw-mill was established by a Dutchman, in 1663; but the public outcry against the new-fangled machine was so violent, that the proprietor was forced to decamp with greater expedition than ever did Dutchman before. The evil was thus kept out of England for several years, or rather generations, but in 1768, an unlucky timber merchant, hoping that after so long a time the public would be less watchful of its own interests, made a rash attempt to construct another mill. The guardians of the public welfare, however, were on the alert, and a conscientious mob at once collected and pulled the mill to pieces.

It is stated that R. Hoe & Co., the New York press builders, have paid the widow of William Bullock \$2,000,000 for the patents he took out on printing machinery.

USEFUL INFORMATION.

Crushing Strength of Bricks.

The resistance of bricks to a crushing force varies greatly according to the quality of the brick. Trautwine, who has experimented considerably with building materials, says on this point that a rather soft brick will crush under a weight of from 450 to 600 lbs. per square inch, or about 30 to 40 tons per square ft., while a first-rate machine-pressed brick will require from 300 to 400 tons per square ft. This last is about the crushing limit of the best sandstones—two-thirds as much as the best marbles or limestones, and one-half as much as the best granites or roofing slates. But masses of brickwork, he notes, will crush under much smaller loads than single bricks. In some English experiments, referred to by this author, small cubical masses only 9 inches on each edge, laid in cement, crushed under 27 to 40 tons per square ft. Others, with piers 9 inches square and 2 ft. 3 inches high, in cement, only two days after being built, required 44 to 62 tons per square ft. to crush them. Another, of pressed brick, in best Portland cement, is said to have withstood 202 tons per square ft., and with common lime mortar only one-fourth as much. The same authority, however, is careful to add the statement that cracking and splitting usually commence under about one-half the crushing loads. To be safe, he recommends that the load should not exceed one-eighth or one-tenth of the crushing load; and so also with stone. Moreover, he notes, these experiments were made with low masses, but the strength decreases as the proportion of the height to thickness increases. He cites the following examples: The pressure at the base of a brick shot tower in Baltimore, 246 ft. high, is estimated at $6\frac{1}{2}$ tons per square ft.; and in a brick chimney at Glasgow, Scotland, 463 ft. high, at 9 tons. Prof. Rankine calculates that in heavy gale this pressure is increased to 15 tons the leeward side. The walls of both are, of course, much thicker at the bottom than the top. With walls 160 ft. high, of uniform thickness, the pressure at the base would be 5.4 tons per square ft. He prudently concludes that with our present imperfect knowledge on this subject, it cannot be considered safe to expose even first-class pressed brick work, in cement, to more than 12 or 15 tons per square ft., and good hand-molded bricks to more than two-thirds as much. —*Manufacturer and Builder*.

PROPOSED OCEAN TELEPHONE.—A Cincinnati company is negotiating with the cable companies for the lease of a line for eight days for the purpose of testing experiments for telephone communication with Europe. It is believed that the new French line will be secured. The arrangements, it is thought, will be completed in a few days. The process upon which the proposed work is to be done is based upon the Oranrough invention of 1868 and the recent Klenin patents. The tests will be made from New York city. Only the combination of the two systems mentioned will be tested, to the exclusion of the Bell, the Edison, or any of the instruments now in active use, as the new company claim that they are actually infringing.

PROF. BAUSCHINGER has lately tested some iron taken from a chain bridge built in 1829, and found that after 50 years of service its strength and elasticity had not altered perceptibly from what they were reported to be at the time they were put into service. The fact that age has little effect on the quality of iron, is likewise verified by the result of tests made by Prof. Thurston of pieces of wire cable of the historic Fairmount suspension bridge at Philadelphia, lately taken down after 40 years of service. The tested pieces were found to have a tenacity, elasticity and ductility fully equal to the best wire of the same size found in the market to-day.

SALICYLIC ACID.—The preservative and antiseptic action of salicylic acid cannot be relied upon when brought into contact with any liquid substance in wooden vessels or casks. The salicylic acid under these circumstances speedily disappears, being apparently absorbed and decomposed by the wood tissue. When this acid is used as an addition to drinking water or wine, the casks must first be coated with pitch.

WHERE ELEPHANTS GO TO DIE.—The elephant hunters of Ceylon and India corroborate Sindbad's story that elephants, when they feel the approach of death, retire to a solitary and inaccessible valley, and there die in peace. Mr. Sanderson, superintendent of elephants to the government of India, admits that no living man has come across the corpse of a wild elephant that has died a natural death.

THE FIRST engineer of the Rhenish railway, which has the longest experience in steel rails, has made a calculation, according to which the average duration of steel rails, when 24 trains pass over them every day, is 30 years, while that of iron rails, with a traffic of 17 trains, is 11 years. Steel rails, according to this calculation, last four times as long as iron rails, although they are but one-third more expensive.

WELDING HORN.—Pieces of horn may be joined by heating the edges until they are quite soft, and pressing them together until they are cold.

Meat Bread.

An interesting observation which bids fair to receive an extensive practical application, is reported to have been made by M. Scheurer-Kestner. This savant discovered the noteworthy fact that meat, when added to bread, during the process of fermentation, disappears entirely, its nutritive principles being incorporated with the bread. In this condition the meat appears to be capable of being preserved for a lengthened period, as the discoverer above named exhibited to the French Academy specimen loaves of meat bread made several years before, which showed no signs of either worms or moldiness.

In the account given of his experiments, he states that at first he used raw meat, three parts of which, finely minced, he mixed with five parts of flour and the same quantity of yeast. Water was added in sufficient quantity to make a dough of proper consistency, and the mass in due time underwent fermentation. In two or three hours the meat had disappeared, having undergone a species of digestion in the fermenting mass, and the bread was baked as usual. The taste of the meat bread thus prepared was disagreeable and sour, an objection that was subsequently obviated by first cooking the meat for about an hour with enough water to afterwards moisten the flour. The meat used for the purpose should be carefully freed from fat, and only enough salt added to give the necessary flavor, as the addition of too much would, by its property of absorbing atmospheric moisture, spoil the bread. The proportions recommended are one-half of meat to one of flour, in which quantities the meat will be thoroughly incorporated during fermentation. Meat bread, prepared with a suitable quantity of yeast, is asserted to make an excellent, nutritious soup for the sick and wounded.

A FRENCH inventor has devised an ingenious electrical low water signal for steam boilers, which indicates the existing water level at any distance from the generator, and when the water has sunk below a certain point rings a signal bell, while at the same time the sign "low water" appears on the indicating tablet.

HON. W. D. BISHOP, formerly Commissioner of Patents, and more recently President of the New York and New Haven railroad, has a carriage mounted on bicycle wheels with India-rubber tires. The wheels were made by the Pope bicycle manufacturing company, and are of steel, nickel plated.

GOOD HEALTH.

Skin Grafting from a Sheep.

The *Chicago Times*, of September 4th, contained a full account of an operation in skin grafting which was performed at the County hospital. The patient was a young man, 23 years of age, named John Filas. A large cancer had been removed from the outside of his right leg near the hip, and the wound which resulted was about 10 inches long and nearly as wide. Nature was healing it so slowly that it was decided she should be assisted, and wisely, too, as the result shows. A previous operation of a similar nature on little Aggie Sheehy was successful, but the vitality in her wasted frame had become so nearly exhausted that her life went out like the light from a lamp exhausted of oil, but it was no fault of the skin transplantation. Filas' frame was strong, and if the experiment should fail he would be none the worse for it. A flap of skin was cut away from the hip of a young sheep, large enough to cover about two-thirds of the wound. It was sewed fast to the natural skin of the sheep on three sides and left attached to the patient on the fourth side. It was expected that while the circulation of the blood of the sheep would keep the flap alive, it would become attached to the exposed surface of the wound on which it rested, and in time be nourished by the blood of the patient. The flap was kept covered for 24 hours. At the end of that time the dressing was removed, and it was found that the tip of the flap, or two inches of it, had died.

Within a few days it became apparent that the remainder of the flap had become firmly attached, the cutting of it away from the sheep was commenced at once, and clippings were made each day. Finally, the sheep began to waste away, and sheep and patient both became very restless. It was thought best to detach the flap from the sheep wholly, and one stroke of the surgeon's knife on yesterday liberated the animal. It is assured that the skin will grow to the man's hip, although some portions of it may yet slough away. If a piece no larger than a silver dollar is finally attached, the fact is settled that skin grafting may be a success. It was not expected at first that less than three operations would be sufficient to supply the patient with all the skin he needed. As soon as the portion now transferred is properly fixed another operation will follow.

PHYSICAL EDUCATION.—Absolute health is only attained when the body is equally developed in all its organs and members. The man with muscles of steel and a diseased heart cannot be said to be in good health, and diseases of stomach, heart and nervous system are often— it may even be said usually—produced by that system of development known as training. At a recent rowing match in Philadelphia, two

plucky lads in contesting boats fainted as soon as the race was over. Their condition, which was apparently good, was actually abnormal, and their systems gave way because the strain which their muscles met was too great for their vital functions. Recently a similar but more serious calamity occurred at Sag Harbor. A Brooklyn lad, who had taken part in a pedestrian contest, when removed from the track, fell down dead. He had prepared himself for walking and running, and depleted his vital organs to build up his limbs. When the strain came, the impoverished and most important part gave way. The severe muscular exercise of college athletes has carried off many fine young men by consumption, heart disease and other disorders, directly traceable to the absurd overwork required of their bodies. There is a limit of human endurance. That limit is reached when the body is impaired in one quarter to benefit special organs. The severity of the test by which athlete prizes are won seems designed rather to award the laurels to him who is least healthy, because more unevenly developed, than to the really best man. —*Brooklyn Eagle*.

DANGER FROM VULCANITE PLATES IN DENTISTRY.—In a recent paper in the *American Journal of Medical Sciences*, Dr. Sexton states that vulcanite plates (worn in the mouth) produce diseases that are often the source of reflex auricular disease. These plates have been in use over twenty years, and are largely adopted. The constituents are caoutchouc, the sulphur required in the vulcanizing process, and vermilion or sulphide of mercury, used as coloring matter. The gradual disintegration of the plate in the mouth liberates a salt of mercury, whose poisonous effects are well known. And the plates are otherwise injurious. At least one-third of all those who attempt to wear them experience great irritation of the mouth, often accompanied by hypersecretion of saliva. The sufferer usually lays aside the plate till informed of the necessity of growing accustomed to its presence by uninterrupted use. Vulcanite is a non-conductor of heat, and the effect of its contact with the highly sensitive tissues of the mouth is to produce hyperemia and inflammation. Another source of injury is the very close contact of these plates, which is maintained by atmospheric pressure, and may favor the absorption of their substance.

PAIN IN ANIMALS.—Prof. J. Rymer Jones is authority for the statement that crustaceans and certain other animals are not susceptible to pain. He says, in a paper on this subject:—"Pain, 'Nature's kind harbingers of mischief,' is only inflicted for wise and important purposes—either to give warning of the existence of disease, or as a powerful stimulus prompting to escape from danger. Acute perceptions of pain could scarcely, therefore, be supposed to exist in animals deprived of all power of remedying the one or of avoiding the other. In man, the power of feeling pain is indubitably placed in the brain; and if communication be cut off between this organ and any part of the body, pain is no longer felt, whatever mutilations may be inflicted. The perception of pain depends upon the development of the encephalic masses; and, consequently, that as this part of the nervous system becomes more perfect, the power of feeling painful impressions increases in the same ratio; or, in other words, that inasmuch as the strength, activity and intelligence of an animal, by which it can escape from pain, depends upon the perfection of the brain, so does the perception of torture depend upon the condition of the same organ."

IS IT SO?—A foreign scientific journal remarks, as a curious physiological fact, that, although open-air life is so favorable to health, yet it has the apparent effect of stunting the growth in early years. Thus, while the children of well-to-do parents, carefully housed and tended, are found to be taller for their age than the children of the poor, they are not so strong in after years. The laborer's children, for instance, who play in the lonely country roads and fields all day, whose parents lock their humble doors when leaving for work in the morning, so that their offspring shall not gain entrance and do mischief, are almost invariably short for their age; the children of working farmers exhibit the same peculiarity. After 16 or 18—after years of hesitation, as it were—the lads shoot up, and become great, hulking, broad fellows, possessed of immense strength. According to these statements, it would seem, that in-door life forces growth at the wrong period, and thus injures. Is it so?

A READY POISON REMEDY.—If a person swallows any poison whatever, or has fallen into convulsions from having over-loaded the stomach, an instantaneous remedy, most efficient, and applicable in a large number of cases, is a heaping teaspoonful of common salt, and as much ground mustard, stirred rapidly in a teaspoonful of water, warm or cold, and swallowed instantly. It is scarcely down before it begins to come up, bringing with it the remaining contents of the stomach; and lest there be any remnant of the poison, however small, let the white of an egg or a teaspoonful of strong coffee be swallowed as soon as the stomach is quiet; because these very common articles nullify a large number of virulent poisons. —*Medical Brief*.

AN EMETIC FOR INFANTS.—A correspondent of the *British Medical Journal* states it as his experience that half a teaspoonful of glycerine acts as a simple and efficient emetic for infants.

The Week.

The week has been one filled with promises of rain, but promises unfulfilled as yet. The signs of the approaching winter have hastened operations in those quarters where winter supplies are to be laid in. The prospectors are coming in from the hills to take a rest till next season. Hydraulic operations are light just now, water everywhere being low. For several weeks past repairs on ditches, etc., have been going on, to prepare them for the winter rains.

The mining news from various parts of the coast indicate continued prosperity and increased vigor in the prosecution of work. New discoveries are everywhere being made, and reduction facilities in the different camps are being increased.

There is no special news in connection with mining matters to which we can refer. The local interior papers are just now very much taken up with political matters, and many of them are more apt to give us their views on national questions than on local affairs.

A REWARD of £1,000 is offered for the apprehension of the murderers of Lord Mountmorris in Ireland.

THE Natoma water and mining company have declared a quarterly dividend of \$1.50 per share, payable on the 5th.

THE Silver King mine made a shipment of 31,000 lbs. concentrations on the 3d.

It is estimated that there are piled up in and around Bodie 100,000 cords of wood.

It is stated that most of the Skagit river mines are abandoned.

The Top-heavy System of Mining.

It is by no means an uncommon thing for mining managements, in an honest endeavor to reduce expenses to a minimum and to see that all outlay of money is made for the best interests of the stockholders, to begin at the wrong end. This is especially true of Eastern organizations engaged in mining in the Pacific States and Territories; and particularly in cases where the supervision is in charge of men sent out from the East. Such companies have a way of cutting down wages to a point where bad feeling is engendered between employees and the managements, and as a natural consequence the work, done in a half-hearted manner, cannot be expected to be as effective as it should; while, at the same time, large sums are expended without murmur in elegant home offices, in high salaries to unnecessary officials, and in costly experiments with new processes and untried machinery which fail when the test of actual practice is applied. There are a large number of Eastern mining incorporations whose office and salary accounts are far in excess of the mine expenditures. Comfortable berths are made for the "promoters" and their friends, while the mine, which after all should be considered the head and not the tail of the enterprise, is expected to take care of itself and to be steadily productive without expense in development.

Hers is a case in point: An Eastern company, operating a large and well-known mining property on this coast, having made unsuccessful attempts to cut down underground wages to a starvation point, managed to effect a general reduction in surface labor. This was all very well, but was carried to such an extreme that efficient men, who could do better elsewhere, could not be hired to work under the new scale of wages. A new engineer was put on the night shift at \$3 per shift of 12 hours—the previous prices had been \$5. The mine was raising water. For three nights all went well; but the fourth night under the new system the engineer lost control of his engine, let her overwind, carried away sheaves, gallowes-frame, etc., and demolished a good part of the roof of the hoisting works. Result: A net saving of \$8, and repairs to the amount of \$1,500. Now it might very easily happen that a \$5-engineer should have met with just as bad luck as a \$3 one, it may be said. Perhaps so; but still, if we were to be hoisted up and lowered down a deep shaft four times a day, we would be inclined to vote for the more expensive man at the lever and brake. The case quoted is an extreme one; but is it without parallel?

A company working a mine on a small scale, say with 10 men, pays \$3.50 per day to each. Instructions from a \$5,000-president in his comfortable \$2,000-office in New York, direct, through a \$2,500-secretary, that the superintendent shall reduce underground wages to \$3 per shift. This secures the magnificent saving of \$5 per day to the company, and shareholders are correspondingly charmed with the economical and business-like management which aims to work the mine on proper, sensible figures.

Again, another Eastern company, having bought a good little mine at a good round figure, devotes \$50,000 as a working capital, to be used in placing the mine in a dividend-paying shape. How is this result sought to be reached? Why, by voting \$11,000 in salaries per year and in ordering a fine and expensive mill, big enough to keep a dozen equally good little mines busy in supplying it with ore. The mill is put up in winter in an arctic climate, with heavy freight charges and under great disadvantages, so anxious is the management to return early dividends to the stockholders. By the time the mill is completed it is found that the working capital is exhausted, that the mine is not in shape to keep a single battery steadily running, and that the accounts are behind hand. Naturally enough, the stockholders, who had confidently looked for a far different state of things, feel reluctant to advance more money, and the whole thing comes to a standstill. Is this the only instance of the kind?

One more case: An Eastern incorporation purchases water rights and gravel claims in Dakota Territory. It is proposed to build a 25-mile flume to develop some wonderfully rich placers, which no one but those interested in the sale know anything about. Economy and sound business principles are to be the rule. Mining expense are to be brought down to a minimum. The construction estimates are carefully scrutinized. Iron piping is to be laid down, 400 miles from the railroad, at New York figures. So much a foot for embankments, so much for ditches, so much for fluming, so much for supplies—no more. Electric lights are to be substituted for keroene or torches for economy. Meanwhile the company raises \$250,000 for the prosecution of this laudable scheme. The president receives a high salary, in requital of which he gets his friends to buy stock; the secretary a satisfactory one, and brokerage commissions are made in due ratio. Now for the outcome of it all. The figures are found to be doctored, the appliances contracted for to have been furnished by inside "promoters," and the whole thing a mistake. A defalcation takes place to add interest to the situation. Is it remarkable that this particular set of stockholders should become disgusted, and believe that even with economy and careful management mining does not pay?

The mining country, the older portion of it, is strewn with wrecks marking similar mismanagement. In many cases, perhaps in most, economy was practiced in the small things and neglected in the greater. The result is that a great number of valuable mines which might have been made profitable are lying idle, and to-day expensive mills and hoisting works are rusting into old iron, silent reminders of what may be termed the top-heavy system of mining. And then the blame is placed on the mines, where it most assuredly does not belong, and the whole industry, which is just as legitimate and as much a business as any other, is made to suffer because of inefficiency and downright swindling in certain hands.

Mining does pay. The proof is tangible.

Bogus Mines.

Of course while there are so many mining companies being organized and put on the market in the Eastern cities, an opportunity is given for setting up fraudulent concerns also. All sorts of dodges are practiced to get money out of a too confiding public, and no propositions are too absurd to find some dupes. Even in California, where we ought to know better, people are found who will help out a man who is going to get gold out of water, and even after they are told how the gold is first put in. The cheekiest attempt we have heard of in a long time, however, is one lately made in New York. *The Graphic*, of that city, on Sept. 22d contained the following item: "The noted London mine is to be opened by Mackay and Fair. The mine was stocked at \$10,000,000, of which \$3,000,000 was voted by the company. Of the balance Mackay and Fair took two-thirds, paying \$184,000 down. A part of this sum was used to pay the floating debt, and \$100,000 was placed in the treasury. A new 20-stamp mill has been ordered, and a force of 140 experienced miners is to be set at work."

The ingenious inventor of the "London mine" took the largest figures he could conveniently use, and the names of the richest and most successful mining men he could find. In this he rather overreached himself. The Virginia Enterprise representative interviewed both Col. J. G. Fair and John W. Mackay, and is authorized to say that there is not a word of truth in their having invested in the London mine; that they do not know where the mine is situated (supposing it to have an existence), and never before heard of it.

The Marin County Mining Failure.

The mining enterprises in Marin county, which made such a stir last January, did not pan out as well as the promoters hoped, but they did as much as we expected and predicted. The San Geronimo mine, with engine, tools and hoisting works, was sold at auction last week under a judgment, the company making no effort to redeem the property.

It will be remembered that work was started in these mines on the strength of "vapor assays" made by a would-be expert of this city, who got more out by his vapor assay than a fire assay showed to be in the rock. Fire assays proved the ore barren, but the vapor assays proved it to average \$65 per ton. Reliable assayers tested the ore by the new method, but found nothing in it at all. The rock was said to be "green," not fully formed, and carrying the metal partly in a "liquid state." A peculiar process was needed to work the ore, also.

In fact the whole thing was one of those foolish speculations which people sometimes go into. The rock was "green," and the people, too. The profits are found in "vapors," the same as the assays found the gold. The only wonder is that so many could be found to put up money for machinery to carry out so very foolish a proposition.

FIRE IN LEADVILLE MINES.—A special to the *Denver Republican*, dated the 5th, says that a fire started at five o'clock in the shaft house of the old Vulcan shaft in the Chrysolite mine, caused by a sick miner dropping a candle. The building was consumed and the burning debris fell into the shaft setting it on fire. The Vulcan connects with the Chrysolite, Little Chief, Amie, Climax and Little Pittsburg mines by levels at a depth of 120 ft., all of which were filled with carbonic acid gas and smoke, driving the men from the work of constructing bulkheads, and 600 ft. away 12 men were overcome by smoke, and barely saved their lives. After great trouble, bulkheads were built, preventing the fire from spreading, and the flames are now confined to a radius of 30 ft. from the Vulcan shaft, and are completely under control. All the shafts are hermetically closed, to exclude drafts, and will remain so for four days. Work will be suspended on all mines for a week and perhaps longer. Nobody is seriously hurt. The damage is about \$20,000, caused by delay of work. All the levels and drifts are full of gas.

An old miner named Charles Brown committed suicide on September 23d on Birdseye creek, Jackson county, Or. He took a good smoke and then blew his brains out with a rifle. He had been engaged in mining for 13 years in that county.

"Reasonable Diligence" in Mining Suits.

The Commissioner of the General Land Office has, in a recent decision, settled that the provisions of the mining law for the adjudication of adverse claims in the courts does not contemplate that the sale of the public mineral land shall be indefinitely postponed upon the simple filing of a complaint. The adverse claim must be prosecuted with due diligence. This decision is given in full in Copp's "Land Owner," from which it is seen that P. J. Lonergan and others filed an adverse claim, against a patent for the Mammoth lods in Colorado, applied for by H. H. Eddy. They filed a complaint in February, 1880, but up to June had issued no summons.

Section 2326 U. S. Revised Statutes provides, "it shall be the duty of the adverse claimant within 30 days after filing his claim, to commence proceedings in a court of competent jurisdiction, to determine the question of the right of possession, and prosecute the same with reasonable diligence, and a failure to do shall be a waiver of his adverse claim." Upon the commencement of such proceedings, all actions in the local offices must be stayed until the controversy has been settled or decided by a court of competent jurisdiction, or the adverse claim waived.

A petition was made to dismiss the adverse claim on the ground that the adverse claimants failed to prosecute their suit with "reasonable diligence" as required by this statute. The Commissioner was of opinion that the negligence in this instance was positive; but it was also clear that the adverse claimants had not commenced their suit in the manner contemplated by the statute. Until a summons is issued the court acquires no jurisdiction over the subject matter in controversy. The law contemplates that the sale of the public lands shall not be delayed by controversies of this character for a longer period than is necessary for the proper legal adjudication of the disputes. In some States the summons may issue at any time after the filing of the complaint. In California, it may issue at any time within one year.

To hold that by the simple filing of a complaint, without having summons issued, an adverse claimant may indefinitely postpone the sale of the public mineral lands, was never contemplated.

The Commissioner says: I therefore allow the motion of the counsel, and dismiss the adverse claim of Lonergan *et al.*, on the several grounds that they have not proceeded with due diligence, and have not commenced their action in the manner contemplated by the law.

ROBERTSON'S PROCESS.—New York *Truth*, of the 23d ult., says: "The controlling interest of the Robertson electric ore reduction company has been sold to Joseph P. Hale, the well-known piano manufacturer, and associates. The price is not stated, but is reported at figures ranging from \$250,000 to \$500,000. At a meeting of the company, held at No. 58 Broadway, yesterday, the following changes were made in the management of the company: Jas. P. Hale was elected President and Director in place of Vernon Seaman, resigned; Henry L. Chandler was elected Secretary and Director, in place of Lindley F. Seaman, resigned; Messrs. William F. Clewell and Theodore Williams resigned their directorships, and Messrs. Charles H. Stone and B. C. Jackson were elected to fill the vacancies; Mr. John A. Robertson continues in his position as director and general superintendent of the company." The New York *Weekly Mining News* says of Robertson: "During his stay in the city, Capt. Robertson succeeded, through the efforts of Mr. Vernon Seaman, in disposing of the controlling interest in his invention, and he returns to the Pacific richer by something over \$100,000 than he was when he came here." Those who know anything about Mr. Robertson's process or the patent under which he holds it, will think he was very lucky to sell at such figures, to say the least. The process has never worked satisfactorily here that we can find, although there was a great deal of talk about it at one time. There are no new principles involved in the process at all, as the New York purchasers will no doubt find when they investigate what the Patent Office calls the "state of the art."

DEATH IN THE BELCHER.—When T. J. Knuckey went to the 3000 level of Belcher on Tuesday morning to relieve his father, Thomae Knuckey, who was running a donkey pump there, he found the old man just above the station in the incline, and overcame with the heat. The young man was alone, and was compelled to go for help or he overcome himself. When he returned his father was dead.

We see by the Nevada City *Transcript*, that during the month of September, various mining companies in that neighborhood shipped to the bay, through Wells, Fargo & Co's office, at that city, the sum of \$134,600. This sum is about \$2,000 more than was shipped during August of this year, and \$50,000 more than in the month of September, 1879.

The shipments by the Seattle (W. T.) Coal Company during September amounted to 11,333 tons, and since January 1st 98, 262 tons.

A Wonderful Ruin in Arizona.

Many have heard of Casa Grande, and have read detailed descriptions of it, and the impressions of travelers upon viewing it. It is certainly one of the most interesting and important vestiges of an earlier civilization upon this coast, and we have thought our readers would like to see a view of the exterior of the structure with some notes concerning its internal construction and arrangement. This view of the exterior is taken from Conklin's "Picturesque Arizona," published by the Continent Stereoscopic Co., of New York. The description of the ruin and the diagrams accompanying it we condense from an article prepared for the *Californian* by Henry G. Hanks, of this city.

The ancient building known as Casa Grande, on the banks of the Gila river, is at this present time the most interesting of all the ruins left by the prehistoric people. Although there are many other ruins of less note which are worthy of careful study, this one is the best known, and is identified with the history of the country. The first mention of Casa Grande is in the account of the explorations of Colorado in 1550. Coronado came northward from Mexico to search out the grand buildings which were reported to exist in the region he explored. The Casa Grande was then a ruin, and the explorer was much chagrined at finding it instead of the golden splendors promised him. Another account describes a visit of Father Kino to the ruin in 1694, and he found traditions among the Indians that the ruin was then 400 years old. Other accounts by visiting priests contain testimony from the Indians which led the explorers to conclude that Casa Grande was built in the 13th century. Later, however, the Indians were closely examined as to the truth of their traditions, and they admitted that they in truth knew nothing of the origin of the building, but that all was wrapped in mystery.

Mr. Hanks, in company with Prof. George H. Cook, State Geologist of New Jersey, and S. P. Van Winkle, also of New Jersey, visited Casa Grande in April, 1879. This remarkable ruin lies about 12 miles from the flourishing town of Florence, Pinal county, Arizona. It stands on a wide-spreading mesa, rising slightly from the main road. The mesquite trees, although low, hide the building until it is nearly approached. For miles distant from the ruin the ground is spread with fragments of broken pottery, in such quantities that it is impossible to reject the idea that the site was at one time densely populated, where now utter desolation reigns. It is natural, under such circumstances, to speculate as to how the people lived; for, if the country was in the same state then as now, the question would be a difficult one to answer. The visitor has ample time to think the matter over from the time he first begins to observe the signs of human habitation until he reaches the building. With our party the conclusion reached was that the Colorado desert may have been once an inland sea, and the climate widely different from the present.

As the traveler approaches Casa Grande he cannot fail to be somewhat disappointed, the more so if he has taken a romantic or poetical view of the published descriptions of that noted building. Instead of the stately edifice he has pictured in his imagination, he beholds only a huge dun colored, almost shapeless mass, looming up strangely from the desolate plain. There is nothing architectural about the structure. It is, at best, but a mud house; though, as he examines it more closely, it seems more and more wonderful, and the mind is filled with conjecture as to the race to which this great building may have been put, and why it stands so lonely and isolated.

The diagram, Fig. 1, upon this page is the ground plan of Casa Grande, on a scale of 20 ft. to the inch. The walls were originally, as near as may be, four ft. in thickness, the exact measurement being three and seven-tenths ft. The highest point, as the building now stands, is 35 ft. It was originally four or five stories high, each of which was eight ft. from floor to ceiling. The extreme length, carefully measured, is 58½ ft., and the width 43 ft. In the north, south, east and west faces of the building there were narrow doors, centrally placed, through which entrance was made into the main compartments, and over each door narrow port holes, decreasing in width from the bottom upward. The diagram, Fig. 2, gives the form of them, drawn to a scale of half an inch to the foot.

The building faces nearly the cardinal points of the compass, the north and south walls bearing north, ten degrees east, which is nearly the true meridian. The interior must have been dark, as the light was admitted only through the before described port-holes. The inner room was, presumably, like a dungeon. The central series of rooms was at least one story higher than the others. From A into E (Fig. 1) there is a port-hole in the second story, from room to room. From E into D there was originally a port-hole of the same size, but it has been filled in. From E to C there is a door, but none from C into B, instead of which there are several circular openings, from eight to ten inches in diameter, extending through the thick

walls and resembling modern stove-pipe holes. They are still perfectly smooth on the inside. What use these singular openings were put to can only be conjectured. Concerning the present condition of this wonderful ruin, Mr. Hanks observes, that the inner surface has remained these long years intact, the smooth face showing no sign of decay. The little wrinkled marks, left when the surface dried, remain the same as when, centuries ago, the builder laid aside his tools, and the work was declared finished. Readers of works written by travelers in Egypt wonder at the accounts given of temple and tomb, whose pictured walls remain as fresh as if newly painted. They are inclined to think, if at all skeptical, that these statements are exaggerated. Yet here in Arizona we have evidences that, in the warm, dry climate, changes take place slowly. It is not easy to understand why the concrete walls should not last a thousand years as well as a hundred. Some parts of the outer surfaces remain as smooth as when left by the builder, while in others the

EXTERIOR VIEW OF CASA GRANDE IN ARIZONA.

tooth of time has gnawed snail-like cavities, like cancer spots. Why this should be the case has caused the writer much thought. For centuries occasional rain storms, and the continued action of the natural sand-blast, have gradually worn away the surfaces, and left their records on the old dun-colored walls. We are apt to

Fig. 1. Ground Plan.

overlook the importance of little things, and may forget that an incessant bombardment, lasting for centuries, may produce great changes, even if the missiles be only grains of sand.

THE Barbee & Walker mining company of Utah paid a dividend of 10 cents per share in New York on the 25th. This makes \$40,000 paid to stockholders. An old and well known Californian, Richard L. Ogden, is resident director at this mine, and exercises a personal supervision over its affairs. The result of his business management is satisfactory, as the figures prove.

POSTMASTER MAYNARD decided Saturday not to suspend the recent order of the Post Office Department forbidding the delivery of registered letters and postal orders to the Kentucky Lottery Company. He declines to reverse the past action of the Department, at least until the United States Supreme Court shall have disposed of the lottery question which is now before it.

THE September product of the California mine was \$92,110.

Silk and Wool Conditioning.

A silk and wool conditioning works has been established in New York city, the first in the United States, although there is in Europe a conditioning house at every large center of silk or wool trade and manufacture.

The "conditioning" consists in drying a definite quantity of silk or wool, by which the net weight of a lot of silk or wool contained in a bale can be obtained, in deducting all over weight for moisture, exceeding 11% for silk, 17% for combed and 18½% for carded wool. These fractions of moisture are those settled on by the Congress of Turin.

The decreaseage is the chemical process or analysis by which the exact percentage of over-weight (gum, grease, etc.) contained in raw silk or wool can be obtained.

Importers or dealers send the bales to be

tested to the conditioning house, with the marks, numbers and weights on a memorandum, and also the name of person to whom the bales are to be delivered. Each bale or part of a bale, after being "conditioned," is provided with a cord or rope, the extremity of which is sealed with a leaden stamp bearing the mark of the

Fig. 2. Porthole.

conditioning house, which is a guarantee of the net conditioned weight, and duly recorded in a certificate sent to seller and buyer. The charge is two cents a pound for any quantity over 50 pounds, and on any quantity less than that \$1 is charged. The certificates of the conditioning establishments of Lyons are recognized for exactitude and fairness, and it is hoped that the new works will obtain similar recognition. The apparatus, scales, etc., have been manufactured specially for this work, and are of the greatest precision.

It is stated that rich lodes of tin have been discovered in Mason and King counties, in Washington Ter. When we hear of some block tin being made we shall believe it. Tin discoveries have been made by the hundreds during the past 10 years, but none of them ever panned out anything yet. We hope this one will.

A DIVIDEND of \$25,000 was paid by the Excelsior water and gravel mining company of Yuba county, California, at New York, Tuesday.

Jupiter's Satellites.

At the last meeting of the California Academy of Sciences a communication was read from Prof. George Davidson, President of the Academy, on the "Visibility of Jupiter's Satellites to the Naked Eye." He says: The seeing of Jupiter's satellites with the unassisted eye is so rare an occurrence, that I wish to place upon record a recent unmistakable case. From the station Monticello, of the United States Coast and Geodetic Survey, 3,125 ft. above the sea, we overlook Berryessa valley on the west and the Sacramento valley on the east. The station is on the highest point of a sharp ridge, trending generally north and south, with many deep gulches on either side. For nearly a month the Sacramento and Coast Range valleys have been filled with dense smoke, and the distant mountain ranges have all been hidden. Even the bold, dark, grand mass of Mt. Helena, distant but 24 miles, was hardly visible through the thick atmosphere. The upper limit of the smoke stratum was quite sharply defined to the eastward; above it the sky was generally clear, but upon the present occasion only moderately so. The weather for some time had been warm and pleasant, without clouds or wind. On the early evening of Monday, September 20th, we were looking at the obscured moon struggling through the dense smoke; Jupiter, at an estimated elevation of about 8 degrees, was emerging from it, and for an elevation of 25 to 30 degrees the whole sky was hazy, and stars of the fifth magnitude, and even some of the larger ones, were not visible to the naked eye. There was not the least radiation to Jupiter, and the planet rose through the smoky but quiet atmosphere into the thinner smoke or haze without radiant points of light to blur its appearance.

With the unassisted eye Professor Davidson detected the third satellite of Jupiter, to the left and below the disc of the planet; but, lest he might be mistaken, he refrained from calling attention to it for some minutes, until there could be no possible mistake, when he announced the visibility of a satellite, but without stating its position in relation to the primary. All the officers immediately announced its visibility and position, but naturally wondered why it should be seen so unmistakably through such a thick, hazy atmosphere. A binocular, or good field-glass, with magnifying power of seven diameters, revealed it, and also showed the other satellites on the sides of the planet, but revealing the first and second satellites with difficulty, until the planet had risen somewhat higher. The third satellite continued visible to the naked eye for perhaps twenty minutes, when the moon rose above the smoke stratum, and the planet began to exhibit traces of radiation, when the satellite was lost to the naked eye, although all the satellites had become much brighter than before in the field of binocular. Upon subsequent nights, after the smoke had in great measure been blown away, with a remarkably clear sky and no moon, but with great radiation to the planet, no satellites have been surely made out with the unassisted vision. The observers who distinctly saw the satellites were Messrs. Lawson, Gilbert and Buckland and also Mrs. Davidson. I have before reported one or more cases of my seeing a satellite of Jupiter, notably once on Mount Diablo in 1876.

Bullion Shipments.*

Since our last issue, we have noticed the following bullion shipments:

Northern Belle, Sept. 27, \$9,493.94; Standard, Sept. 27, \$26,634.51; Northern Belle, Sept. 29, \$4,389.85; Christy, Sept. 30, \$8,136; Argenta, Oct. 4, \$2,100; Standard Con., Oct. 4, \$50,624.93. Con. Virginia for month of Sept., \$82,225. California, Oct. 3, \$64,000. Bodie Con. for Sept., \$26,060; Standard Con. for Sept., \$130,432; Noonday for Sept., \$27,895; North Noonday for Sept., \$18,333; Belvidere for Sept., \$13,882; Dudley for Sept., \$1,746. Tiptop (Arizona), Oct. 5, \$30,000; Richmond Con., Oct. 2, \$23,086.

*Desiring to make our list of Bullion Shipments as complete as possible, we will be thankful to receive from mining Superintendents and Secretaries notice of all bullion shipments from their respective mines.

THE California mine yielded 109 tons ore last week, assaying \$21.60 per ton. A shipment of \$64,000 in bullion was made on the 3d, and there is \$28,110 more at the Virginia office.

WORK in the north branch of the Sutor tunnel has been abandoned on account of a difficulty with the managers of the north end mines.

THE Consolidated Virginia mine produced 936 tons of ore last week, assaying \$27.76 per ton, and has \$17,166 in bullion at the Virginia office.

BUT one mining location has been recorded in Bodie district, during September, and that one an underground location in the Bodie

Bingham Pyrites.

"There is not a mine in Bingham sinking," said a miner from that camp to our reporter yesterday. That means much to a miner. There is no prospecting ahead for ore reserves; no attempt to determine the question so important to Bingham's future, viz; the condition of the ledges below the pyrites.

In 1872 the old Utah company tried to sink a shaft, and quit because the water encountered could not be baled out with a bucket. The Winnamuck, under the management of Pinedo, started a shaft later, and for some cause not yet explained, work was suspended and the machinery sold.

The Last Chance, after wrestling with insufficient machinery and the Flagstaff muddle, quit sinking at a depth of 200 feet from the tunnel level, although there was ore, good ore, at the bottom of the shaft.

While the Spanish mine was turning out its millions from a ledge seventy-five feet wide, there was no attempt made to go below the water level, and it remains to-day high and dry—a wreck.

Men begin to realize now what is required to keep a paying mine on a paying basis. The sod turned last spring will not do for next year's crop, and the miner who does not keep his ground cultivated ahead of his work will come out at the diminutive end of the horn. It is only a question of time, unless new levels are opened up, when the upper workings are all stopped out and the mine then, as the Bingham mines are said to be, worked out.

It is well known that in order to handle the water encountered in sinking, a single compartment shaft is worthless. And yet in view of the many failures of those who undertook to accomplish anything with such shafts, the Bingham miners still persist in the same folly. While the money thus wasted comes, perhaps, from the pockets of those who can afford it, yet every failure affects the interests of all. The successful sinking of one deep shaft in Bingham would enhance the value of every mine in that camp. It would not only do that, but also give employment to several thousand miners.

There is not a practical miner in Utah who is not satisfied that below the pyrites is good ore. European miners have proved this, and American smoke indicates fire the same as smoke does the world over.

With a railroad connecting the camp with the outside world, a tramway running by the dumps of nearly all the mines, the mines in the hands of wealthy owners and the best talent in the country to draw from, there is no sense or reason for Bingham's nonproductiveness.

The Last Chance has passed into the hands of the old company, and with the encouraging look in that company's shaft, we would not be at all surprised if the solution of Bingham's future does not come from that quarter.—*Salt Lake Tribune.*

Paradise and Willow Creek Mines.

Mr. Stanley a practical mining man from Virginia City is visiting the Paradise and Willow Creek mines. He is not a capitalist, and does not desire either to hold or purchase, but is simply looking for a suitable location to put his 10-stamp quartz mill. He would, if desirable, consolidate his mill with any good prospect promising an adequate return for the venture, and owners of such claims would do well to make his acquaintance. In the extensive mineral belt that skirts Paradise valley, there are many ledges carrying low grade ores in abundance, and where the water and fuel privileges are second to none in the State. Some of these ledges are of huge proportions, but owing to the character of the ore, they have not been extensively worked by prospectors, who as a rule confine their operations to ores that will pay to ship. Experience teaches us that these low grade ore bodies are the most permanent; and the time will doubtless come, when the attention of capitalists will be turned toward developing them instead of the big things which almost invariably prove "big bills" in the end, as in the Colorado and other places. The poor prospector, however, must look for something rich on top, and leave the development of low grade ledges to capital. His scanty means are insufficient to meet the expense attending any extensive development, where the ore is not rich enough to market, and consequently our mammoth low grade ledges, with the vast treasure contained in their depths, are undisturbed. We can recommend Mr. Stanley to our mining men, as a man who has had large experience in the working of ores, and a gentleman in whom the utmost confidence may be placed with safety.—*Paradise Reporter.*

BEAVER CREEK DISTRICT.—The work done in this district during the summer has been considerable. Messrs. Graham, Jones, Fiddler, McIlvain and Heiherger have been the principal workers. The latter has a good prospect known as the Bull-Domingo. The workmen have sunk the shaft to the depth of 60 ft. and have struck a vein of gold-bearing rock that assays three ounces to the ton. With the striking of the vein came a flow of water that effectually drove the workmen out. Mr. Heiherger does not intend to let the matter rest there, and has purchased a hoiler and ejector, and will pump the water out so as to continue development on what may prove a very valuable property.—*Fairplay Plume.*

INCERSOLL

ECLIPSE ROCK DRILLS.

The Most Economical Air Compressors in the Market.

MINERS' HORSE-POWER.

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The Power is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX,

49 Fremont St., S. F.

GUINEAN'S UNIVERSAL REFRIGERATOR.

It will keep Provisions of all kinds, Meat, Game, Butter, Fruits, Etc., for a longer time and in better condition than any other. All sizes, suitable for family use, Restaurants or Hotels.

Scientific and Practical Books
on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1887.

This work is unequalled by any other published, embracing the subjects treated; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ore and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 135 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3.00 coin, postage free.

Books for Miners and Millmen.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arsenurets, and gold and silver ores generally, with 120 lithographic diagrams. 1887. This work is unequalled by any other published embracing the subjects treated. Post-paid, \$7.50. Printed and sold by Dewey & Co., S. F.

AARON'S TESTING AND WORKING SILVER ORES.—Illustrated, 114 pages. 1876. A useful and practical work, free from technicalities and extremely serviceable for miners' use. Post-paid, \$2. Published and sold by Dewey & Co., S. F.

Mining & Scientific Press
Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free.

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW on SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Quarto. 234 Illustrations.

By ROBERT GRIMSHAW, Ph. D., M. E.,

Member of the Jury on Wood-working Machinery at Paris Exposition of 1878.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand, sash, Mulay, jig, drag, circular, cylinder and band Saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, swaging, gunning, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 96 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copiously indexed.

Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the price is this date made \$2.50, postage paid.

A Card from Architects.**The California Architect and Building Review.**

Office, No. 240 Montgomery Street, San Francisco, Cal.

It is with pleasure that we publish the following from prominent Architects in this city:

Believing that a Journal of the kind is a necessity on this coast, and judging from what has appeared in the "Quarterly Architectural Review," we are led to believe that the CALIFORNIA ARCHITECT AND BUILDING REVIEW will be worthy of generous support and encouragement. We therefore pledge our cordial sympathies, personally, and hope that the enterprise will receive kindly recognition and liberal support from all Architects and Builders and the public generally. (Signed) David Farquharson, Wright & Sanders, E. H. Williams, Thos. J. Wells, F. Huera, John Marcus, B. McDougal & Son, Wm. Moser, Wm. Curlett, Meeker & Banks, W. O. Hoagland, S. & J. Newsom, B. Hendrickson

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

Columbus Mining District, Nevada.

[From our Travelling Correspondent.]

EDITORS PRESS:—The mines here are confined mainly to one great mineral zone, nearly 10 miles in length with an average, perhaps, of half a mile in width. Its general course, easterly and westerly; the interlying ore veins taking a similar strike with a dip to the north. Formation, a porphyritic clay slate, in places more or less elicitified and grading off into quartzite.

A few mines are opened in the vicinity of Columbus. The principal operations are near the west end of the belt, where are found nearly 1,000 inhabitants, chiefly in Metallic City and Candelaria—two thriving villages scarcely a mile apart.

The lithographic map sketched by Mr. D. Corcoran, of Candelaria, and forwarded with his compliments, will give you a very correct view (looking southward) of the last named place, bearing in mind its rapid growth since the sketch was taken, as also of the ground and hoisting works of

The Northern Belle Mine.

Coming into existence in a dry and desolate land where all supplies were dear, where wood and water could scarcely be bought for gold, horn of toil, nurtured in hardship, this child of fortune has ever taken the lead in the district, and to-day stands as fairly queen among the fairer of her most favored sisterhood on the coast.

Only the most salient points in her career need be given. The mine has attained the depth of 1,700 ft. from the summit of the mountain; width of lode 100 ft.; of ore bodies from 2 to 30 ft. Gross bullion product, \$7,000,000; actual value in gold coin, \$6,000,000; disbursed in dividends, \$1,625,000; average yield per month, \$100,000; yield last month (Aug.), \$150,000. Two large 20-stamp mills with a Stedfeldt furnace attached to each have been erected at Belleville, from 7 to 8 miles from the mine; capacity of the mill 110 tons per day; men employed at mill and mine, 250; number of tons of salt used, 250, and 1,000 cords of wood. As bright as this picture seems, the mine has had her dark days. One year ago on the 1st of September, she was in debt to the amount of \$133,000.

Since that date the indebtedness has all been liquidated, and \$100,000 paid in dividends, leaving \$112,000 now in the treasury. Prospects of the mine are said to be good, giving promise of doing nearly as well as in her palmiest days, the gross product of the past year footing up the neat little sum of \$1,242,000.

So long as the quantity and quality of ore holds out under the present management, stockholders may rest securely and may look for many a dividend. The Silver Star, adjoining the Northern Belle on the west, is represented to contain ore similar in every respect, and from \$30 to \$100 per ton in value. Depth on the lode, 200 ft. Coming next on the north side of the belt is

The Enterprise.

Two lodes have been cut by a tunnel 640 ft. in length. The ore is here considered low grade, running from \$25 to \$40 per ton. The time will come at no very distant day when all now will be worked with a profit. The tunnel is now being pushed for the back or principal lode, which is expected to be reached with a run of 60 ft. more. It is said to contain some very fine ore, giving upwards of \$100 in assays. It has been opened by a shaft on the surface to a depth of 50 ft. The vein from 20 to 30 ft. wide. The Vanderbilt, adjoining on the west, is said to be a good deal broken up in present workings. The ground is thought to be favorable, but a much greater depth will probably be required before finding a permanent ore body. Next in order is

The Victor.

A promising mine of three locations, known as the Victor proper, the Magnet and the Chloride. Deepest work on dip of vein 550 ft. from croppings. Two lodes have been cut by a tunnel into the mountain from the north. The

ent be worked with profit. Full width of back lode not ascertained as no cross-cutting has been done. It is evidently large, as from five to six ft. of very fine ore is now being extracted along the hanging wall. Drift east and west aggregate 400 ft. The ore is worked at the Rhode mill, New Boston, yielding somewhere from \$50 to \$70 per ton. Considerable bullion has been already shipped. It is looked upon as one of the coming mines of the district, having a first-class location.

The Mount Potosi Series

Lie south of the Victor near the west end of the belt. They are very favorably situated on the western slope of Mount Potosi, and consist of several locations, among which are the Star of Nevada and Mount Potosi proper, into which a tunnel is now being driven. Some very fine ore has been cut in its course, and there is every reason to expect richer and larger ore bodies the further it pierces the heart of the mountain. The greatest depth yet reached in any of the workings is 300 ft. A number of veins cut from 1 to 6 ft. wide. Ore worth from \$30 to \$40 per ton—too low a figure to pay without a mill on the ground. Some ore of a much higher grade has been encountered, 324 tons recently worked at Belleville giving pulp assays as high as \$84 per ton. Near the Mt. Potosi and above the Victor is the Candelaria (No. 1), the property of W. J. Sutherland, Esq., of Columbus, shaft down 50 ft., and represented to have a 2-ft. vein of pay ore. It promises to be a rich field for operations, all the indications in this quarter being of the most favorable character.

The New Jersey Group.

Is in a good location on the eastern slope of Mt. Potosi, although work has been suspended, it is hoped, only temporarily. A mine that has milled 30 tons of ore, going to \$280 per ton, ought not to lie idle long.

The Lucky Hill

Is situated on the lucky side of the mineral zone, nearly opposite the Enterprise, a ravine dividing the locations. A tunnel cuts the vein at right angles about 100 ft. from its mouth and 45 ft. from the surface, where 58 ft. of solid ore is encountered, averaging \$25 per ton. The tunnel has been extended 300 ft. further, passing through low-grade ore mixed with porphyry the distance of 58 to the foot wall, making a total of 110 ft. between walls, these both well marked. After passing the south wall a hard elicitified slate comes in, gradually shading off into the softer clay slate toward the end of the tunnel.

A tunnel has been sunk 238 ft., following the hanging wall, and a drift from tunnel level 100 ft. east along the same wall. Average assays of ore from a point in the winze 130 ft. from surface \$57, showing a very marked improvement on the attainment of greater depth. Capacity of hoisting works sufficient for 800 ft. of depth.

The Equator.

Comprising the Yellow Chief, Richmond, Welch, O'Keefe and Burning Moscow, embrace one of the largest and most favorably situated properties in the district, lying immediately east and adjoining a portion of the Northern Belle ground, where good ore was taken out up to the dividing line. Two tunnels were started with the view of prospecting the ground, developing some good ore averaging \$169 per ton, but not being very favorably situated, the work was discontinued until late spring, when the company commenced sinking a joint shaft, a further account of which will appear after a brief notice of

The Metallic.

This mine is bounded on the west by the Equator and on the east by the Mount Diablo, the eastern line of claim extending to within a short distance of the famous Mountain Boy lode, discovered two years since, and being one of the Mount Diablo series of veins. An incline was sunk 350 ft. and two drifts run on the vein from the 300 level, developing some good ore, but the ground at the bottom of incline and also in the drifts being found somewhat broken, the exploration in this manner were discontinued for the purpose of joining the Equator in sinking a shaft which is known as

The Equator and Metallic Joint Shaft.

This is one of the important enterprises in the district. It is one of the best and most economical modes of mine development, and the example might be followed with advantage by other companies. It is about time the old method of running a tunnel 1,000 ft. to attain a depth of 100 ft. should be abandoned. First-class hoisting works have been erected with good shaft house, blacksmith and carpenter shops and everything put in good shape. The machinery has sufficient capacity to sink 1,500 ft. The shaft is 4x4 and has now attained the depth of 500 ft., well timbered all the way down. At the 400 ft. level a station has been cut with a view of starting a drift through the Equator ground in the direction of the Northern Belle, from which crosscuts will be made to prospect the mine. As soon the shaft reaches the depth of 600 ft. a drift will be run into the Metallic and crosscutting for the veins vigorously pushed.

Sutherland Claims.

Lying in the center of a triangle formed by the Mount Diablo and Metallic mines and the Northern Belle shaft, W. J. Sutherland, Esq., owns and is working, as we are informed, some very valuable claims, said to be pronounced by experts as among the best properties of the district. They are worked through a double compartment shaft, now down 230 ft., from which he will crosscut as soon as the machinery

The Malloy.

The property of Mr. P. Malloy, of Metallic City, is a promising prospect, cropping out in bold relief in the rear of his place in the middle of the town above named.

The Southern Nevada

Is in a good neighborhood, immediately east of the Northern Belle on the north side of the belt. The mine lies partly within or near a greenish dyke of harder rock than the ordinary formation, cutting some distance into the mineral zone at this point. It bears some of the marks of a green slate, but is more likely a variety of slate, somewhat altered by the same cause that metamorphosed the surrounding slate. It is rather a favorable sign than otherwise, for ore cropping out within or on either side of such a formation ought to be well concentrated. The future will determine the question.

The incline is 230 ft. on the vein. Some of the ore is represented as rich, assays running from \$25 to \$675 per ton, working value not learned.

The Holmes.

East of the Belle and south of the Nevada, is probably very similar to the last, as the formation and contour of the ground are much alike. No details were secured.

The Belding.

Next in order east, shows a 10-ft. vein at the depth of 76 ft., of a very promising character. It is hoped that the crosscut from foot of winze on the 210-ft. level will soon develop a rich body of ore.

This letter is perhaps long enough. You may look next week for some account of the

Mount Diablo.

A very prominent mine on the west end of the belt, as also of others of more or less importance lying farther east. A review of what has been given shows that there is much rich ore here—many very fine prospects as yet but little developed, and an immense body of low-grade ore that will eventually pay to work.

THE Nevada State fair, which closed at Reno Saturday, was poorly patronized, the

In the Whole History of Medicine

No preparation has ever performed such marvelous cures, or maintained so wide a reputation, as **ATREX'S CHERRY PECTORAL**, which is recognized as the world's remedy for all diseases of the throat and lungs. Its long continued series of wonderful cures in all climates has made it universally known as a safe and reliable agent to employ. Against ordinary colds, which are the forerunners of more serious disorders, it acts speedily and surely, always relieving suffering, and often saving life. The protection it affords, by its timely use in the throat and chest disorders of children, makes it an invaluable remedy to be kept always on hand in every house. No person can afford to be without it, and those who have once used it never will. From their knowledge of its composition and effects, physicians use the **CHERRY PECTORAL** extensively in their practice, and Clergymen recommend it. It is absolutely certain in its remedial effects, and will always cure where cures are possible.

FOR SALE BY ALL DEALERS.

Pocket Mining Atlas,

Containing the principal mining districts in the United States. Compiled from the latest official surveys and the most authentic sources by Edwin Bolitho. Sent, post-paid, on receipt of \$1. Address, Dewey & Co., 202 Sansome St., S. F.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omissions of agents.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the **MINING AND SCIENTIFIC PRESS** which we will sell for \$3 per (half-yearly) volume. In cloth and leather binding, \$5. These volumes, complete, are scarce, and valuable for future reference and library use.

J. O. COLMERNIL is requested to report to this office. He went to Humboldt County, Cal., about May 4th, 1880. His Agency for this paper has been revoked for good and sufficient reasons. Mr. C. is a heavy set man, of dark complexion, weighing some 175 pounds, or more.

Chew JACKSON'S BEST Sweet Navy Tobacco.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

DIVIDEND NOTICE.

Howell's Improved White Roasting Cylinders.
REVOLVING CYLINDERS AND ORE DRYERS.
Hoisting and Pumping Machinery.

MOREY & SPERRY,

MANUFACTURERS OF

Gold and Silver Grinding and Amalgamating Machinery

HOWLAND'S PULVERIZER Takes the Place of the Cumber-
some Stamp Mill and can be put up in one day ready for work.

IT HAS BEEN FULLY PROVED AND TESTED.

It weighs complete, 7,000 pounds. It costs \$1,250 ready for the belt. Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. The wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies, Iron Work complete for Wood Frames, also

SPERRY'S
WROUGHT IRON FRAME
FOR STAMP MILLS.

Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores, Wet or Dry Crushing Mortars.

MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

STEIGER & KERR'S CONTINUOUS DISCHARGE AND GRINDING PAN.

This pan is designed to receive ore direct from a rock breaker, and reduce it to the fineness necessary for amalgamation, thus taking the place of the ordinary stamp battery. The cost of this Mill places it within the reach of all; and one point of advantage not to be overlooked is the fact that the cost of erection, which adds so much to the expense of the stamp mill, after it leaves the foundry is, in this case, reduced to a fraction, as the Mill is complete in itself, and requires no expensive foundations, bed logs, battery frames, etc., but can be placed in position in a few hours after it arrives on the ground, without the aid of skilled labor. The simple arrangement, durable as it is simple, is a most important improvement in the working of gold ores, as it enables parties to construct and erect a mill at half the cost of a stamp mill, and with a great saving of time, and size of mill building. Each pan is capable of reducing 10 tons of average ore in 24 hours, the ore being first broken in a rock breaker, small enough to go through a half-inch screen. There is an important point in the action of this Mill, to which we desire to call the attention of miners and millmen. We allude to the grinding and scouring action on the gold before it is discharged. The value of this point cannot be over estimated, and it is not necessary to do more than mention the fact, as it will be at once recognized by all competent millmen who examine the pan in operation, and especially by those who have had to deal with tarnished or rusty gold, as it is commonly called, and which is often encountered in our mines, and which is such a cause of loss. The plan of feeding is the same as in the stamp mill, either an ore feeder or hand feeding being adopted, as may be desired. Parties interested in mining and milling can see the Pan in operation by calling at the OCCIDENTAL FOUNDRY, STEIGER & KERR, 137 First St., S. F.

In consequence of spurious imitations of
LEA AND PERRINS' SAUCE,
which are calculated to deceive the Public, Lea and Perrins
have adopted A NEW LABEL, bearing their Signature
thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE
SAUCE, and without which none is genuine.
Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper.
Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London,
&c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

STEEL CASTINGS

FROM 1-4 TO 10,000 lbs. WEIGHT.

True to pattern, sound and solid, of unequalled strength, toughness and durability.
An invaluable substitute for forgings or cast-iron requiring three-fold strength.
Gearing of all kinds, Shafts, Dies, Hammerheads, Crossheads for Locomotives, etc.
15,000 Crank Shafts and 10,000 Gear Wheels of this Steel now running prove its superiority over all other Steel Castings.
CRANK SHAFTS, CROSSHEADS and GEARING, specialties.
Circulars and Price Lists free. Address

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade

PATENTED IN THE UNITED STATES PATENT OFFICE.

THE CALIFORNIA POWDER WORKS,

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and HERCULES Powder.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

DUNHAM, CARRIGAN & CO.,

LIGHTNING SCREW PLATES

WITH TAPS, DIES AND COLLETS COMPLETE.

The Huntington Oscillating Stamp.

We illustrate on this page the Huntington oscillating stamp mill. This is an entirely new invention, and one which is out of the usual track, being really a stamp without stems, cams or tappets. It consists essentially of a bifurcated arm, at the upper end of which is the pitman for oscillating it back and forth. At the lower ends are the shoes, which rest on dies having inclosed sides or back pieces. As the arm is oscillated, first one shoe strikes and then the other alternately. By the peculiar construction a grinding as well as a crushing action is maintained. The shoe strikes and crushes the rock and then slides along a little, grinding the crushed rock under it. This combines therefore the action of the stamp and arastra. The engraving shows the operation so plainly that a detailed description is unnecessary. This machine is very simple and economical, being durable and working effectively. From its peculiar construction the power required is comparatively light. Among mining men this machine is attracting a great deal of attention. It is a cheap mill, an \$50 lb. hammer costing \$500, while one with 1,200 lb. hammer costs \$600. For double mills, working from same shaft, \$50 is deducted from price of second stamp at above figures.

The alternate rocking of the bifurcated weight brings first one leg in contact with the ore and then the other, the ore being thus rapidly crushed, and the whole weight of the stamp never having to be lifted. When, however, the weight begins to fall all the weight of both legs is imparted to the blow that the falling one delivers. The lower shod ends of the legs always keep in the proper position, since the rounded corners of the mortar give them a tendency to move towards the center at each blow. This peculiar motion is attended with a grinding or pulverizing action as the stamp is shifted in another direction.

The machine is so arranged that an automatic ore feeder may be used with it. Very little power, comparatively, is required to operate the bifurcated stamp or weight, while its action is very effective. One stamp acts as a fulcrum to raise the other, the action being alternate.

There are four of these mills at work at the California Water and Mining Co.'s mines, El Dorado county; two at Oro Fino mine, Shingle Spring; two at Hornitos, Mariposa county. There is also one at Forbestown, Butte county; one in the Black Hills, one in Idaho, one in Washington Territory, three on the way to Arizona, etc. A number are now being made at the foundry, 213 Fremont St., where Mr. F. A. Huntington, inventor and manufacturer, has his headquarters, where further information can be had.

GREENVILLE QUARTZ MILLS.—In order that the outside world may have some idea of the importance of the Greenville mining district, the Greenville (Lincoln Co.) *Bulletin* gives the number of stamps in the various mills in that immediate vicinity. Those now running or that will be in a few days, with the names of the mills, are as follows: Green Mountain, 92; Gold Strike, 39; Plumas National, 30; Kettle (Cherokee), 20; New York, 10. Total, 191. Stamps that will probably soon be running, are the following: Union and Indian Valley, 56; Crescent, 32; Monitor, 10; total 98. Making a grand total of 289 stamps. What other mining district in the State surpasses it?

PLACER COUNTY MINES.—The mining industry in the vicinity of Dutch Flat shows a great deal of activity. The *Forum* says: It is a noticeable fact that at the close of a successful mining season a greater number of claims are taken and patented than at any other time, hence the unusually large number this fall. All persons who have old claims or who have taken up new ones are of the same opinion, that the next season's run will be even more prosperous than the one just closed. Extensive preparations are being made on all sides for an expected long and paying season in the future.

Mazourka Canyon Smelting Ores.

Mazourka canyon, opposite Independence, in the Inyo range, says the *Independent*, offers a better field to-day for smelting operations than any other district in the State of California. The canyon begins nearly opposite Independence, and runs nearly due north for a distance of about 12 miles. A good wagon road with an easy up grade runs its entire length. The head of the canyon is called Badger flat, which is not exactly a flat, but low, rolling hills, thickly covered with nut-pine wood interspersed with a few cedars. This is the source of the wood supply for Independence, and the quantity seems almost inexhaustible. The canyon cuts the Inyo range obliquely, and the general formation on the west side is mostly granite and syenite, and in this granitic rock has been found numerous veins of gold-bearing quartz, and some of them exceedingly rich, though none of them have been ex-

plained more than 100 ft. in depth, owing to the lack of the necessary capital to develop. On the east side, which is the main mountain range, the formation is entirely different, being mainly lime and slate, and it is in this formation that the smelting ore is found. Here a large number of locations have been made, and some of them have been prospected to a considerable extent, with very encouraging results. The character of the ore is carbonates and sulphurets of lead or galena, assaying from 40% to 50% of lead, and nearly all of these ores carry both gold and silver, the yield in silver is from 50 to 75 ozs. per ton, and about \$10 in gold, making the value of the ores from \$75 to \$100 per ton. From the developments made, there are evidently extensive deposits of these ores to be had, and they lie in just the right kind of formation for large bodies to be found. Among the claims that have been developed, are the Eagle, the Giant, the Cumberland, the Josephine and the No Name. These claims have from 20 to 30 tons of good ore on their dumps, and plenty of ore in sight, awaiting a smelting furnace to show up its metallic riches. The facilities for smelting in Mazourka canyon are first-class; plenty of water can be had within one or two miles of the mines; charcoal can be delivered at a furnace by the quantity for 20 cents per bushel; wood can be had at from \$5 to \$6 per cord; there is plenty of skilled labor in the country, and the produce raised in the

valley is comparatively cheap; in fact, there is every inducement for some individual, or company to erect smelting works. A smelter erected on a liberal basis, and prepared to buy ores from the miners at a fair price, would induce a large number of men to go to work taking out ore and opening their mines, and the smelter would be reaping large profits in buying the ores and turning them into bullion. In the Inyo range, mild weather prevails through nearly all the winter months; the snow falls only a few inches in depth at a time, which soon disappears, and there is no obstacle to the prosecution of active work during every month in the year. That Mazourka canyon is not half prospected is proved by the recent rich discoveries there, and we confidently expect at no distant day to see the smoke from the stacks of the smelting furnaces gracefully curling above the foothills across the river.

CURIOSITIES.—The miners in the Monte Cristo mine at Spanish Peak, find numerous petrifications, the trees standing in every shape in

THE HUNTINGTON OSCILLATING QUARTZ MILL.

the clay. One of the most singular ones is a tree cut off by a drift from the main tunnel, which is, or was, about 30 inches in diameter. It stands perpendicular in the clay-pipe, and has a hollow place where the heart of the tree was located, some 3 or 4 inches in diameter, in which the light of the candle reveals the grain of the wood. It is a hard, sandy formation, slightly red in color, and to tally unlike any specimen of petrified timber we have ever seen. The round shape, the hollow heart and the bark are, however, conclusive evidence that at one time it was a tree; and besides it is entirely different from the clay which surrounds it. Another curious place in the mine is a crack or crevice in the bedrock in the deepest worked place in the mine. This crack is not more than 4 inches in length, and 1/2 inch in width, but a steady stream of air rushes out of it, which will blow out a candle instantly. The question is, what does it connect with?—*Plumas National*.

BUT little work is now being done in the once famous camps of Florence, Elk Creek, Jordan Creek or South Boise, Idaho. The placers on Snake river and on various tributaries of the Salmon, however, have paid very good wages to all the men employed for the past two or three years, with plenty of good ground still to be worked.

Smoking in Mines.

It seems strange that it should be so difficult to prevent men smoking in mines, more especially in coal mines, where there is danger of explosion. Even the most seasoned smoker cannot go into a close drift where a pipe has been smoked without nausea. The stale smoke will sicken almost anyone. There are usually stringent rules against smoking, but men break them and even risk their own and other people's lives for the brief enjoyment of a pipe.

It is a matter in which the government intervenes in Europe, and it is not left to individual companies to adopt and enforce a rule. Smoking in mines is in direct contravention to the Mines Regulation Act. How they serve those who break the rules is shown in the following incident.

Roht. McFarlane, laborer, pleaded guilty before Sheriff Byrne, to having on the previous morning smoked in the Cadzow colliery, Hamilton, near a place where explosive gas is known to exist, and is issuing from the coal in great volume, and safety lamps are used, and thus endangering the lives of 30 persons then employed in the mine. He stated that he was employed filling water, a cold, wet job, which caused him to be, for the most of his time, sitting waiting till the water gathered, and he went to a manhole, where the lamps were lighted, and lighted his pipe after scratching two matches. The procurator-fiscal could not admit the accuracy of this. He explained that there was no lamp cabin below ground; that this place was a stone mine, across a dike; therefore into a new field, where, if the mine is fiery at all, gas was given off in great quantities. There were 30 men employed, all, for greater safety, with Stephenson's safety lamps. The ventilation of the pit was so complete that the gas was carried off as it was made, but any impediment to the free passage of air would make the gas explosive in the course of a few minutes. The rules regarding lights and smoking were enforced most rigorously; indeed, no man was known to go within the gate of the colliery with a pipe in his possession. The sheriff asked if there was any mitigating circumstance in the case. The fiscal answered in the negative. He thought it was about the worst case that had occurred in all his experience. The sheriff said he was impressed firmly with the idea that there was only, in this district, among those fiery mines, one mode of dealing with these cases. If he could find any mitigating circumstance, he would not send a working man to jail for so long a period; but when he considered the lives which the man recklessly put in jeopardy—his own fellow-workmen—and that were he to make the punishment less than he had previously done he might be leading to most disastrous results; he firmly believed it was his duty to insist upon the same punishment he had previously inflicted, viz., three months' imprisonment.

CONSIDERABLE prospecting is now being done in the hills, near Bishop Creek, Inyo Co., so at no distant day new mining towns are liable to spring up like "mushrooms in June," making the lucky ones rich and prosperous.

IN Atlanta district, Idaho, the ore is silver bearing. Several Eastern and one Indiana company own valuable mines in this district, which they have constantly worked for the past 14 years.

MANY persons unacquainted with the topography of Idaho imagine it to be a barren, cold and inhospitable region generally, something like Alaska. Such an idea is extremely erroneous.

THE name of the miner who was burned alive in his cabin at Grass Valley on the 6th inst., was Charles Mulheren, and not O'Brien, as at first supposed.

SINCE the first discovery of gold in Idaho, on Oro Fino creek in 1860, the total yield of the Territory has aggregated the enormous sum of \$90,000,000.

CORRESPONDENCE.

We admit, unreservedly, opinions of correspondents.—Ed.

Columbus Mining District, Nevada.—No. 2.

[From our Traveling Correspondent.]

COLUMBUS PRESS:—Nature seems always to follow some general plan. In this sense, her laws are invariable. There is, however, usually a certain pleasing variety in her operations, caused often by very slight differences in surrounding conditions. The Constock, if rightly apprehended—is one vast mineral zone, the ore being found in veins or chimneys in the midst of the interlying porphyry, and holding a course somewhat parallel at the different depths attained. Such is the case with the ore veins of Candelaria, with this difference, however, that here they are, perhaps, better marked and the ore bodies more readily traced. But at this point the parallel masses. The Constock is a well determined contact vein or lode. What may be the nature or the proper designation of the lode or vein of this section, is a question that probably yet remains to be decided. In the light of present developments, there is little reason to pronounce them true fissures in any ordinary use of the term. They are in most cases too well defined to be styled banded veins, such as are frequently found in the Himalayas. And there is as yet no very clear evidence of a contact between different formations. There is a rock, it is true, unlike the slate formation at one point on the north, that puts part way into the same. It looks more like a false slate than any other, and might be taken for a variety of slates, or for one of the forms of hornblende. It is barely possible that this magnesian rock may hereafter be found to extend, and even, some think, the northern boundary of the belt; and thus along it a contact lode, its general similarity to the Constock suggesting such an inference. One thing is certain. Nothing anomalous has ever yet been written in the great book of nature. If we fail to understand, it must be set down to lack of sufficient data or capacity to read and interpret aright. But what matters it whether it is a contact, bedded vein, true fissure or what not, as long as gold ore holds out as now on the lowest levels reached, or while a million of bullion or more is annually shipped, and

Northern Belle

continues to gladden as many hearts and houses with her regular monthly dividends. Nor is this all. Other mines promise soon to be put on a paying basis.

The Mount Diablo

In particular may be mentioned as a star of the first magnitude, just now beginning to appear above the horizon. The mine is very favorably located south of the dyke previously alluded to, immediately above Metallic City, and a mile from Candelaria. It ranks next to Northern Belle in bullion production. A very considerable amount was extracted years ago, one excavation, near the surface, yielding as much as \$488,000. The present depth of double compartment shaft is 350 ft. Levels are opened at the 150, 250 and 350 ft. stations. Now drifting and stopping on the first and second levels—the first producing about 45 tons per day. A very thin body of ore is understood to have been struck not long since on the second level. The third level has been run 150 ft., and has yet to make about 40 ft. more before cutting the lode. The value made of ore and ledge matter together is fully \$50 ft.

The best pay ore on the 150 ft. level is from 2 to 10 ft. wide, averaging \$100 per ton. The best, if assayed, would yield as much as \$700. On this level there are hundreds, if not thousands of tons, of lower grade ore that can be made to pay a profit with cheaper mining and milling facilities. The company is now shipping at the rate of 60 tons per day to one of the Northern Belle mines, the result of which will probably soon be heard from.

Anticipations as to the future of the mine are at present running high. Many supposed to be well posted, are of the opinion that she is destined at no very distant day to rival, if not eclipse, her dividend-paying neighbor to which allusion has more than once been made. So much for her.

The East Mount Diablo

Adjoining the above, has had little development on the surface. Lying between the Mount Diablo on one hand and the East, Jackson on the other the character of the ground will soon be determined by the explorations now going on in these mines. The Mount Diablo on one of her levels is now within 150 ft. of the lode, and said to have at this point a good strong vein.

The East Jackson's Share

Is also within 150 ft. of the east end of the East Mount Diablo's ground, and as both properties belong to the same company, prospecting will be carried on simultaneously.

The Jackson's incline shaft is now down 150 ft., following the vein.

About 85 tons of ore looked upon as first-class have been taken out, estimated to mill \$100 per ton, and the mine is considered a fine prospect.

The Candelaria (No. 2).

South of the Gen. Jackson and East Mount Diablo, has recently struck very fair ore. Shaft, 80 ft. deep and drift on lode, 150 ft.

The Mountain Girl

The property of Messrs. Sutherland, Murphy, and McLean, is situated due east of the Mount Diablo hoisting works. It is the first extension of the Denver or the famous Mountain Boy lode. Shaft now down 230 ft., and work rapidly pushed with two shifts.

The owners are very sanguine as to results.

The Windsor

North of the Jackson, some years ago extended ore that milled as high as \$300 per ton. Very good ore is said to have been found at the depth of 160 ft., the shaft on the way down, cutting veins from 8 to 10 inches wide, the ore giving assays from \$20 up to \$300 per ton.

The Bertha

Near the Windsor, is at present taking out ore worth \$300 per ton, assay value. Preparations are making to erect machinery.

The Eastern Belle

Running parallel with the Windsor, has a shaft 100 ft., a north drift 150 ft., and one south 170 ft., both through vein matter, but neither cutting the lode. An incline on the vein struck ore at the depth of 50 ft., that assays from \$20 to \$40.

The New England

Some distance further east, comprises several claims, being 1,500 ft. long by 1,400 ft. wide. It has been opened by shaft 120 ft., by incline, tunnel, winze and drifts, developing ore bodies in different parts of the claim. The ore, as to character, is classed as chlorite and magnesian. About \$60,000 worth was extracted at one point, working from \$250 to \$300 per ton. The mine is now being worked through a shaft and incline aggregating a depth of 130 ft., from which level an east drift has cut a body of ore, the extent and value of which are not yet known, two assays going respectively \$113 and \$212 per ton.

On the Columbus side of the mountain, W. J. Sutherland, Esq., has recently had some claims incorporated under the name of

The Highland Ohio

The ore is represented to be rich and the prospects unusually flattering.

The Tilden

One mile from the town of Columbus, was discovered as early as 1868, and yielded soon after a very considerable amount of bullion. It lies in the granite, and the rock is understood to be more than ordinarily rich. It has been relocated, and the work is expected to be vigorously prosecuted. On account of the water to be handled, hoisting works will be required.

Having now given a brief sketch of most of the principal mines of this great mineralized zone, it may be well to give some account of

The Two Great Drawbacks

To successful operations in the district, more particularly at the west end. Wood and water are both scarce and dear. Water sells at from 5 to 10 cents per gallon—is hauled from Belleville and Columbus, the distance of from 8 to 10 miles. When it is remembered that there are thousands upon thousands of tons of low-grade ore here, which could be made to pay with mills on the ground and cheap power for hoisting purposes, the magnitude of these drawbacks must be at once apparent.

Proposed Remedy.

It is understood that a franchise has been granted to a company to supply Candelaria with water. The source of supply is from springs about 10 miles distant. The company claims to be able to furnish 15 times the amount now used—a sufficiency not only for family use, but for all milling and mining purposes. The water has been tapped by a tunnel 1,000 ft. in length. The estimated cost is put somewhere from \$40,000 to \$50,000. It is understood, also, that an abundant supply of water can be obtained from another source, if needed. It will cost something more, the distance being greater. Scarcity of wood will be remedied as soon as the narrow-gauge railroad reaches Candelaria, and much of the ore can be shipped to Carson river or other points to be worked, if a sufficient number of mills are not in the meantime constructed for the purpose on the ground.

A. C. K.

MOUNT GREEN. All that region of mountainous country, on and about Mt. Grant, Esmeralda county, Nev., bears the same name as the mountain peak, and still there is a vast difference in the mineral character of the country within the space of a very few miles. For instance, on and about Mt. Grant proper, as well as about Squaw creek, a short distance from it, all the gold and silver-bearing area are more or less mixed with baser metals, while between the two lies a belt of free gold ore. On this middle belt, six miles south of the foot of Walker lake, and seven miles south of the proposed town of Milbrae, which is to be the shipping point for Bodie from the Carson and Colorado railroads, is located the Golden Eagle mine, owned, in part, by Bodieites, and near this is the somewhat famous Big Indian mine, both containing large quantities of free gold ore of high grade. The Big Indian people have sent to the Constock to purchase a mill, having an abundance of ore in sight. The Golden Eagle has also a large quantity of high-grade ore in sight, and several other claims on the "free belt" have fine prospects. *Radio Standard.*

Northern Esmeralda.

Revival of Operations in Old Camps.

A representative of the *Bodie Free Press* spent last week in the northern portion of Esmeralda county, Nevada, about 50 miles north of Bodie, and about 60 miles south of Virginia City, visiting Cambridge, Rockland, Pine Grove and other points.

The most extensive mining operations now in progress in northern Esmeralda are at Cambridge, at which point is situated two or three series of ledges and a 10-stamp mill. Most of the mines and the mill are the property of ex-Gov. H. G. Blandel, and are under the immediate personal supervision of Col. S. W. Blandel. The mines are located in a low range of granite hills, running northerly and southerly, which rise up from the plain between the range of mountains in which is situated Pine Grove and Rockland to the west, and the range of which Mount Grant is the principal peak to the east. The Cambridge mines have been worked to some extent for 15 or 20 years past, their discovery dating prior to that of the Constock lode. Numerous shafts have been sunk to a depth of from 100 to 150 ft., and the Wheeler Bros., who owned largely in the district years ago, when it was known as the Salt River district, erected a small mill on the banks of the East Walker river and worked the ores with more or less success. The ores are, except those taken from the Blackhorse mine, low grade and somewhat difficult to treat successfully. They contain copper, galena and iron in earbo-nate and other forms. In the precious metals gold largely predominates over silver.

A little over a year ago Gov. Blandel purchased the mines, which comprised the Williams, Blandel, Walker River, Black Horse and El Dorado, together with a ranch of bottom land on Walker river, about a mile distant from the mines. He replaced the old Wheeler affair with a 10-stamp mill of the modern sort, fully appointed with all the latest appliances, and a model of convenience and economy in working. It is run by water power, supplied by a large race from the Walker river, about three-quarters of a mile in length, from which, also, water is supplied to irrigate the ranch. In connection with the mill are two large boilers, used merely to supply steam for the pans, an office, assay office, retort room and manager's residence.

The mines are on three parallel ledges, about 1,000 or 1,500 ft. apart, and are each 600x1,500 ft. Each of the ledges shows separate and distinct characteristics, the Williams ledge showing the greatest tendency to baseness, and the Black Horse being the nearest free milling. The latter vein contains very rich ore, which is found in successive kidney-shaped chimneys. Its color is usually a reddish brown, and free gold can be seen on nearly every piece. The ledges are traceable on the surface for a mile, or even a greater distance. The granite formation is of a highly silicious character, and is filled with mica. The mines are easily worked, and there being a steady grade thence to the mill, ore is transported for reduction at a very light expense. The mill was completed last year, but, with the exception of a few experimental runs, has not been put to work regularly until this season. Some difficulty has been experienced in securing the services of an amalgamator competent to work the ores, containing as they do bases of various kinds. Dr. Matthews, who has a very extensive fund of scientific knowledge, is now attending to this work, and is meeting with considerable success.

The Virginia and Bodie line of stages runs up to the Cambridge postoffice, which is also Wells, Fargo & Co.'s office, which is in charge of Capt. J. H. Williams, as postmaster and express agent. Capt. Williams owns a mine known as the Reese; Capt. Williams and E. R. Willis the Willis mine, and E. R. Willis the Samant. The situation of the mill and ranch is very pleasant to the eye. Shut in on every side with low granite hills, the mountains further away forming a dark background, the willow-banked river running through the green meadows impart to the place the character of an oasis in the desert. It is 2,000 or 3,000 ft. lower than Bodie, and the climate is correspondingly mild, snow in the winter time seldom remaining on the ground more than an hour or two. Altogether Cambridge, while being a peculiarly pleasant place of residence, gives promise of becoming a profitable bullion-producing region.

Rockland

About eight miles to the west of Cambridge, in the same range of mountains in which is situated Pine Grove, is Rockland, a camp which years ago was a lively one, as its little graveyard, in which 8 or 10 were buried with their boots on, fully attests. The principal mine in this district is the Dolores, from which has been produced about \$200,000. This mine was purchased by Gov. Blandel four or five years ago, and a 10-stamp mill was erected by him. The fact that no snow fell for two or three years, caused such a drought that sufficient water could not be obtained to run the mill. As a consequence, operations have been almost suspended in the district since that time, with the exception, perhaps, of a little prospecting. Work has been resumed on the Dolores mine this summer, and Col. Blandel has taken out some ore and shipped it to the Cambridge mill for reduction. The mine has been developed by six different tunnels in the mountain about 100 ft. apart, all of which, except the last, was run on the ledge. The last was run in at right angles with the ledge, and intersected it at a distance from its mouth of about 750 ft. The

two tunnels above the lower one are each about 1,000 ft. in length. The ore is found in chutes in the fissure, which is continuous throughout, these being 100 or 150 ft. in length, and from 2 to 12 or 15 ft. in width. Immense chambers have been etched out in the mine on different levels, but there is still in sight an immense showing of ore. The ore produces gold and silver, which is found principally in sulphurets, and runs from \$20 to \$150 per ton. Specimens of rich rock from the lower tunnel have assayed as high as \$1,500. The ledge runs nearly north and south, and pitches east, and, as it is plainly indicated on the lower tunnel, is a contact vein, the east rock being a sort of quartzite and the west a porphyry.

Ex-Senator A. Garrard owns an extension of the Dolores, which has been developed to some extent by a tunnel, from which some very rich rock has been taken.

The only appearance of life about Rockland now, is the small force of men at work in the Dolores. The houses in the once busy little town are all deserted—the express office, post-office, saloon, stores and residences—and the open doors ewing on their rusty hinges give out a most doleful and ghastly threnody.

Pine Grove

North of Rockland three or four miles is Pine Grove, which has a record of bullion production of a million and a half of dollars. Here are situated two 10-stamp mills, one of which is now at work. The principal mines are the Wilson and Wheeler—the former being the only one in which anything is doing at present. The Wilson has a tunnel about 1,500 ft. in length, and is owned by David Wilson & Sons. The tunnel is but 200 or 250 ft. below the surface at any point. Sixty ft. below this tunnel, however, another tunnel is being run. The ore in this mine is found in successive chambers. The ledge formation is very wide, the veins of ore usually being found about four ft. in width, on the hanging wall. The mine is worked on the tribute system—that is, the miners pay a certain fixed price for working the ore, and the owners receive a proportion of the profits above the cost of milling. The Wheeler has been a large producer, but at present work is suspended on that property. The town of Pine Grove appears to be a thriving little community. No whisky is allowed to be sold in the place. All work is suspended on Sunday, and but for the isolation from the main routes of travel, it might be a very pleasant place to live.

There are several other districts of more or less importance in northern Esmeralda—including Washington district and Mount Grant, and the prospects for extensive operations in that section at no distant day are remarkably good.

Belmont and Adjoining Districts.

It would be a good thing, says the Belmont *Courier*, if the owners of closed down mines in this and adjoining districts would dispose of them to parties who are willing to develop them in a thorough manner. It has been the custom in this country to coyote under the grass roots, and after working out the ore above water level, close down for an indefinite period. Tybo (at one time one of the liveliest bullion-producing camps in Nevada) is under a cloud just now from this ruinous system of working, and Tybo has as good mines as any in the country if the company will only develop them properly. Belmont is pretty much in the same fix. There is only one company working at present—the Belmont. Work in this mine is progressing satisfactorily and a good quantity of fair ore is being extracted from the stapes. The concentrating mill will soon be ready to start operations. Depth is necessary to develop the mines, both here and in Tybo, and to attain this a large shaft must be sunk and heavy machinery put up. Jefferson is almost as quiet as a graveyard from the effects of mismanagement, and yet there are mines there that ought to be paying handsome dividends instead of being shut down. Ophir canyon is in the same fix as Jefferson, and yet before the fault occurred in the ledge, hundreds of thousands of dollars were taken out of the mines there. At Grantsville the mines are being opened in a thorough and systematic manner, just as mines always should be opened. The Alexander company will soon have 40 stamps pounding away on ore from this celebrated mine, and there is enough of it already exposed to keep this mill running for the balance of our natural lives. The Rockliffe company is erecting hoisting works on its valuable property, and it is the intention to sink a shaft and thoroughly develop the mine. These mines have never been assessed. The mines at Morey are being worked in a satisfactory manner with flattering results. The Rockliffe mine at Spanish belt is opening up splendidly and promises to develop into one of the biggest mines in eastern Nevada. In Philadelphia district if two or three companies will unite and sink a combination shaft they will undoubtedly open up bodies of ore that will make handsome returns to the stockholders for the outlay. Mining men of acknowledged ability are satisfied that the mines of this district can be profitably worked to a great depth.

PANORAMA AND COUNCIL.—A. F. Powers, one of the largest mine owners in Butte county, has purchased the right to use Francher's amalgamator on any mining ground that he has. He made the purchase after having given it a thorough trial and finding that it would be just what his interests claimed that it would be. —*Oreville Mercury.*

MECHANICAL PROGRESS.

WELDING BY PRESSURE.—M. Spring still continues his researches on welding by pressure. He has already submitted more than 80 solid spherized bodies to pressures ranging as high as 150,000 pounds per square inch at various temperatures. The results, which have an important bearing upon geology and mineralogy, are of considerable interest. He has found that all crystalline bodies proved capable of welding, and in the case of bodies accidentally amorphous the compressed block showed crystalline fracture—crystallization had been brought about by pressure. Softness favors the approximation of the particles and their tendency to their placing themselves in the direction of the axis of crystallization. The amorphous bodies, properly so called, fall into two groups, one of substances like wax, which weld easily, and the other of substances like amorphous carbon, which do not weld. The general result is that the crystalline state favors the union of solid bodies, but the amorphous state does not always hinder it. Prismatic sulphur is changed by compression to octahedric sulphur; amorphous phosphorus seems to be changed to metallic, and other amorphous bodies change their state. In all cases the body is changed into a denser variety, whence may be inferred that the state taken by matter is in relation to the volume it is obliged to occupy under action of external forces.

A NEW SCREW.—It is a well-known fact that the great bulk of the screws used are driven in with the hammer, and given a turn or two with screw-driver, to bring them flush. Recognizing this fact, an ingenious inventor for many years has been working upon a new screw, which is adapted for driving, and which enters the wood without tearing the grain. The gimlet point is dispensed with, and a cone point substituted. The thread has such a pitch that it drives in with barb fashion, offering no resistance in entering, but firmly resisting all attempts to withdraw it except by turning it out with the screw-driver. The head is flat, but in setting it up two nipples, or square shouldered projections, are raised in it by the one operation. The screw-driver takes hold of them more easily than it does of the customary neck, and holds quite as firmly, and when driven flush the projections on the head are not in the way, and do not disfigure it. It is claimed that this screw can be made one-third cheaper than ordinary screws, the principal saving being effected in the doing away with the necessity of sawing the neck in the head.—*Design and Work.*

PUDDLING OF IRON.—Mr. E. Harris, the President of the South Staffordshire Mill and Forge Managers' Association, in a paper which he has just read before the institute on the puddling of iron, said that the schemes tried to prevent smoke, save fuel, etc., might be counted by scores, but none of the recipes had been so effectual as to secure a general adoption. It was a mistaken theory to suppose that because iron was fibrous in the puddled bar it would be fibrous in the finished bar. Often enough the puddled bar was crystallized, and no matter how many times this class of iron was worked over again, fibers could not be developed. The "hot short" iron was as much to be guarded against as the "cold short," for whilst the engineer in constructing a bridge or building a vessel dreaded the "cold short" iron, the blacksmith and the boiler-maker equally feared the "hot short."

The use of blowers under steam boilers is being gradually abandoned. The disadvantages are numerous. It requires a larger amount of power to run them, and unless the mill is situated away from other buildings causes great annoyance and danger from sparks and cinders. A plating mill at the South End, Boston, was set on fire five times in as many years by sparks. Another mill was set on fire, caused by back draft into the boiler-room. The action of the blast on the crown sheet of boilers is like a blow-pipe, always striking in the same spot, and it is safe to say boilers will last double the time running by natural draft. A mill near Boston started with blowers under six new boilers, and had to renew the crown sheets within two years' time.

SIZE OF GOVERNOR PULLEYS.—The *Manufacturer and Builder* gives the following rule for fixing the size of governor pulleys: To find the diameter of the governor shaft pulley, multiply the number of revolutions of the engine by the diameter of the engine shaft pulley, and divide the product by the number of revolutions of the governor. To find the diameter of the engine shaft pulley, multiply the number of revolutions of the governor by the diameter of the governor shaft pulley, and divide the product by the number of revolutions of the engine.

A REMARKABLE CASTING.—The most novel exhibit shown at the Brussels national exhibition by the Seraing works is a certainly remarkable casting. It consists of what is practically the whole cast-iron work of a marine engine, with a pair of cylinders about 20 inches in diameter by 20 inches stroke, cast in one piece—bed-plate, condenser, air and feed and bilge pumps, standards, cylinders and exhaust pipe.

HOT POLISHED SHAFTING.—Since the early part of 1876 the Akron Iron Co., of Ohio, have given much attention to the manufacture of hot polished shafting by a process which, while it yields a product possessing important advantages, is such that only the best raw material can be employed. This fact is in itself a guarantee against any inferiority in the shafting turned out, and has contributed to its growing popularity with the manufacturers of agricultural implements, in the construction of which light—and, therefore, strong—parts are eminently a necessary factor. The process of the manufacture of hot polished shafting affords special facilities for turning out true work, and for making it to the gauge desired without having recourse to the lathe. A circumstance which makes the product of the improved process particularly suitable for line and counter shafting, is that it does not spring or warp in key seating. The well-known effect of polishing iron at an elevated temperature—that which gives Russia sheet iron its peculiar blue finish—is produced by the process adopted in this case. A magnetic oxide, adhering firmly, is superficially formed, affording protection against the formation of rust. We have had occasion to examine specimens of the shafting referred to, which show in a characteristic manner the presence of the coating thus obtained, and which, in conjunction with the other peculiarities noticed, render it worthy of the attention of those interested.

DIFFICULT CASTINGS.—The Ames Manufacturing Company of Chicopee are making some of the most difficult iron castings ever attempted in this country, in the shape of engine tubs for the Seymour Paper Company of Windsor Locks, Conn. One was made a few weeks ago, and a second has just been turned out, both jobs being accomplished without accident. The tubs are nineteen ft. long, eight and a half ft. wide, and thirty-two inches deep, the sides and bottom averaging about seven-eighths of an inch thick. They have heretofore been made in four pieces and riveted together, as it was thought impossible to make the whole in one casting. Many old molders, hearing that the work was to be undertaken, prophesied a failure, and iron-workers from as far off as Pittsburg, Penn., came to see the first tub cast. The Seymour Company are to have several more made, believing that though they cost a good deal to make and to handle, they will last, when once in place, as long as the mill stands. The Ames Company are to be congratulated on their success, as the work was very difficult. Eight tons of metal had to be melted for each tub, and a weight of 45 tons was piled upon the cope or covering to hold it down when the iron was poured into the big mold.—*Paper World.*

RENDERING IRON FIRE PROOF.—Iron, as is well known, is in some respects the very best material that can enter into the construction of a building, and in other respects it is the worst; of the latter phase we would speak. It is hardly necessary to refer to the fact that iron pillars and joists are very susceptible to the influence of heat, and that a fire of small magnitude will soon warp and twist them to such an extent that the fall of the whole structure becomes a certainty. Iron will endure pressure and strain under ordinary circumstances, but will quickly succumb to the influence of heat. To guard against this and to place it in the front rank of materials used in construction, it is proposed, with reason, too, that in all buildings in which iron is a factor, that it be encased in some non-conductor of heat. Terra-cotta has been suggested as the remedy. It may detract from the appearance, but that should be subsidiary to safety. If iron can be rendered a salamander it is certain to rise in favor, because it possesses all the other desirable properties required in the construction of buildings—lightness, strength and beauty.—*Insurance World.*

SHOULD SAND BE USED IN WELDING?—A correspondent of the *Blacksmith and Wheelwright*, writing from Glen Falls, N. Y., says: "The rule among smiths generally seems to be that the more sand they can get on in welding the better, the idea being that the iron will be heated more evenly by this process. Some time ago I got out of sand and could get no more for a time. After I had worked a while without it I did not want any more, and have not used it since. Some of the reasons for not using it I will name. The forging is cleaner, and it takes less time to do work without than with sand. I have done just as good work since I stopped using it as before, and have done it in less time. I would like the opinion of the trade on this subject. If it can be shown that there are reasons for using sand which will more than balance the reasons for not using it, I shall be glad to know them. The sand used by smiths here is from molders' castings."

NOTES ON STEEL.—Steel merely hardest is hardened on the surface, while in steel that has been tempered the exterior is the softest. In the one case because the surface was cooled in advance, in the other because it was heated in advance. Steel which has rusted can be cleaned by brushing with a paste composed of $\frac{1}{2}$ oz. cyanide potassium, $\frac{1}{2}$ oz. castile soap, 1 oz. whiting, and water sufficient to form a paste. The steel should first be washed with a solution of $\frac{1}{2}$ oz. cyanide potassium in 2 ozs. water.

SCIENTIFIC PROGRESS.

Gould's Comet.

Prof. Klinkerfues, of Gottingen, has published a letter on Gould's comet, discovered last February at Cordova. His object is to point out that the probable identity of this comet with those seen in 1843 and 1863 need not be rejected because it does not appear to have been seen, although so conspicuous an object between those years. So nearly does it approach the sun (within, indeed, about 100,000 miles of its surface) that the resistance to its motion when at perihelion is likely to be sufficient to produce a very considerable diminution in its period of time, the case being, in fact, one of resistance from the sun's atmosphere itself, and not merely, as has been conjectured in the case of Encke's comet, from the ethereal medium existing in space. Hence there is nothing extravagant in the supposition that the resistance of the part of the corona within which the comet passes may be quite sufficient to diminish its period of revolution from 175 years to 37 years. Carrying this view still further back, Prof. Klinkerfues contends that it is probable that the same comet may be identical with one seen and described by Aristotle in the year B. C. 371, when that philosopher was only 13 years old and still living in his birth-place, Stagira. He considered it likely that while the period of revolution from B. C. 371 to A. D. 1668 was 2,039 years, it was diminished by the resistance of the sun's atmosphere, first to 175 and then to 37 years; and, further, that it has at the late passages through perihelion been again decreased to 17 years, so that it may be expected that the comet will return in the autumn of 1897.

MALLEABLE NICKEL.—Dr. A. Fleitmann, of Iserlohn, Germany, writing to a German scientific paper, gives the most detailed account yet published in regard to his well-known method of making malleable nickel and cobalt by the addition of magnesium. Herr Fleitmann has found that nickel containing zinc is, to a certain degree, malleable, and that such an alloy can be rendered malleable by smaller proportions of magnesium. In order to make the nickel zinc alloy, the pure oxide of nickel is very thoroughly mixed with 5% of oxide of zinc, the whole being reduced to metal which contains about 4% to 5% of zinc. The presence of zinc is said to act upon the nickel in a remarkable manner, a malleable metal being produced, even without the addition of magnesium. It is likely that the brittleness of melted nickel is due to the presence of some cyanogen, and that both magnesium and cyanogen act by forming volatile cyanides, and possibly by decomposing any carbonic oxide present. After the addition of 1-20th% of magnesium, the nickel zinc alloy is claimed to become completely malleable, and to be capable of being welded both to nickel and to iron or steel. Messrs. Fleitmann & Witte have rolled sheet nickel two ft. wide and have turned out nickel-plated sheet-iron or steel. Thicker plates of nickel are welded to the iron or steel plates, heated to a high temperature, and are rolled out together in the ordinary way without scaling off. It should be noted that steel sheets true nickel-plated cannot be hardened. The nickel-plated sheets are said to take a fine polish.

THE NEW PHOTOPHONE.—The editor of *Popular Science Monthly*, in alluding to Mr. Bell's new instrument, the photophone, says: "Though it is said that light produces the effect, yet this is not strictly true; for a thick plate of India-rubber, if interposed in the path of the acting beam, intercepts all the light but still permits the passage of the radiant force which produces the sound. It is some dark ray accompanying the light proper that does the work. The experimenters have found also that other substances share with selenium the property here made available, though in a less degree. We thus have another step in the rapid progress of molecular physics and the marvelous interaction of forces which is sure to stimulate experimental inquiry, though whether it will confound past conclusions and clear up past mysteries it is impossible to say. And equally impossible it is to say whether the photophone will turn out to be of any practical use. But it is certainly unsafe to deny it. The telephone is but a thing of yesterday, and was at first supposed to be only a curious plaything. But already 'there's millions in it.' How far it is developed as a business is shown by the fact that a convention of 21 companies meets at Niagara to look after the interests of this new and rapidly extending means of intercommunication."

THE COURSE OF A LIGHTNING FLASH.—Prof. Tait, of Edinburgh, insists that when people think they see a lightning flash go upward or downward they must be mistaken. The duration of a lightning flash is less than the millionth part of a second, and the eye cannot possibly follow movements of such extraordinary rapidity. The origin of the mistake seems, he says, to be a subjective one, viz., that the central parts of the retina are more sensitive, by practice, than the rest, and therefore that the portion of the flash which is seen directly affects the brain sooner than the rest. Hence a spectator looking towards either end of a flash very naturally fancies that end to be its starting point.

Salt Lake in Ancient Times.

It is well known that the ancient water surface of the great Salt Lake of Utah once covered a vast area of country, probably more than ten times that covered by the lake at the present time. The most conspicuous vestiges of that great body of water are found in its extensive shore lines, which are, even to this day, most unmistakable in their character. It is also known by three indications that the surface of the lake was at one time fully 1,000 ft. above its present level. The lake at that early period most undoubtedly had an outlet to the ocean, and much speculation and no little research has been indulged in to fix upon the locality of this outlet, but as yet without any generally satisfactory result. The *Popular Science Monthly* sums up the results thus far as follows:

Mr. G. K. Gilbert maintained, in the *American Journal of Science* for April, 1878, that the point of overflow was Red Rock pass, Idaho, at the north end of Cache valley; that the discharging stream descended through Marsh valley, and thence continuously to the Pacific ocean; and that, flowing over soft material at first, it gradually excavated at the pass a channel more than 300 ft. deep, and lowered the level of the lake by the same amount.

Dr. A. C. Peale controverted Mr. Gilbert's conclusion in a subsequent number of the *Journal*, and held that the original altitude of the Red Rock pass was considerably below the highest level of Lake Bonneville; that the original shore line exists in Marsh valley, at the north end of the pass, as it does in Cache valley at the south; and that the real point of discharge, when the water stood at the Bonneville level, was about 45 miles north of Red Rock pass. Mr. Gilbert has, within a few months, revisited Marsh valley and Red Rock pass, and other points near the former supposed outlet of the lake, and gives in the May number of the *Journal* his reasons, derived from his later observations, for adhering to his former conclusions.

He assumes to determine the character of the body of water which has occupied a given spot, whether it was a stream or a lake, from the nature of the terraces left in the valley. There are stream-terraces, and wave-terraces, and delta-terraces, and others, all marked by distinct features. A lake should leave wave-terraces or delta-terraces. In revisiting Marsh valley, he traversed it from end to end, making a careful search for the terraces of the ancient shores, selecting the most favorable stations and lights he could get. He saw stream terraces and displacement-terraces of considerable magnitude, and a few inconspicuous terraces due to unequal erosion, but no wave-terraces and no delta-terraces. He made a special examination of two terraces referred to by Dr. Peale in support to his views, but did not recognize in them any features inconsistent with the opinion that they are stream-terraces. He consents to reconsider his original location of the outlet of the lake at the time of the beginning of the overflow, and assigns it to a position two miles north of Red Rock.

Mr. Gilbert Thompson, an expert topographer, visited the northern limits of the lake in 1877, while ignorant of the results of Mr. Gilbert's examination, and came to the same conclusion that he had reached.

A CURIOUS fact has been brought out by the examination of the artificial diamonds obtained by Mr. Hanney, to the effect that nitrogen was present in chemical combination with the carbon. Mr. Hanney is inclined, therefore, to believe that his diamonds were formed by the decomposition of a nitrogenous body, and not by the decomposition of the hydro-carbon. The diamonds, moreover, were not found when nitrogen was absent; but the successful experiments are still too few, and the evidence too vague, to justify drawing any conclusions on this subject.

A NEW SHADE FOR ELECTRIC LIGHTS.—A French inventor, M. Clemandot, has devised a shade for reducing the glare of electric lights, which he claims to be much more economical than ground glass globes. He makes his lantern of glass tubes filled with finely spun glass threads or glass wool. By reflection from the glass threads the light is given the desired diffusion, with a loss of illuminating power not exceeding 15%, against 30% or 40% with opal or ground glass. The natural blueness of the electric light can be corrected by tinting the glass tubes or the inclosed wool.

An improved method of stopping engines, says the *Electrician*, has recently been devised. The main object of the device is to enable any child or unskilled persons in any part of a mill to stop the engine in case of accident. The action is exceedingly simple. By touching a spring similar to the spring of an electric bell, an electric ball is set in motion. The ball drops and shuts one of the valves, which prevents the steam from escaping, and the engine is brought to a stand-still.

PHOSPHORESCENT LIGHTNING.—Dr. Phipson takes sulphide of barium, or some other substance which is rendered phosphorescent by the solar rays, and incloses it in a Gessler tube, through which he passes a constant electric current of a feeble but regular intensity. He claims to obtain in this manner a uniform and agreeable light, at a cost lower than that of gas.—*Les Mondes.*

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Columbus Mining District, Nevada.—No. 2.

[From our Traveling Correspondent.]

EDITORS PRESS:—Nature seems always to follow some general plan. In this sense, her laws are invariable. There is, however, usually a certain pleasing variety in her operations, caused often by very slight differences in surrounding conditions. The Comstock—if rightly apprehended—is one vast mineral zone, the ore being found in veins or chimneys in the midst of the interlying porphyry, and holding a course somewhat parallel at the different depths attained. Such is the case with the ore veins of Candelaria, with this difference, however, that here they are, perhaps, better marked and the ore bodies more readily traced. But at this point the parallel ceases. The Comstock is a well determined contact vein or lode. What may be the nature or the proper designation of the lode or vein of this section, is a question that probably yet remains to be decided. In the light of present developments, there is little reason to pronounce them true fissures in any ordinary use of the term. They are in most cases too well defined to be styled bedded veins, such as are frequently found in the limestone. And there is as yet no very clear evidence of a contact between different formations. There is a rock, it is true, unlike the slate formation at one point on the north, that juts part way into the zone. It looks more like a talc-slate than clay slate; might be taken for a variety of slate, or for one of the forms of hornblende. It is barely possible that this magnesian rock may hereafter be found to extend, and form, as some think, the northern boundary of the belt; and thus stamp it a contact lode, its general similarity to the Comstock suggesting such an inference. One thing is certain. Nothing anomalous has ever yet been written in the great book of nature. If we fail to understand, it must be set down to lack of sufficient data or capacity to read and interpret aright. But what matters it whether it is a contact, bedded vein, true fissure or what not, so long as good ore holds out as now on the lowest levels reached, or while a million of bullion or more is annually shipped, and

Northern Belle

Continues to gladden so many hearts and homes with her regular monthly dividends. Nor is this all. Other mines promise soon to be put on a paying basis.

The Mount Diablo

In particular may be mentioned as a star of the first magnitude, just now beginning to appear above the horizon. The mine is very favorably located south of the dyke previously alluded to, immediately above Metallic City, and a mile from Candelaria. It ranks next to Northern Belle in bullion production. A very considerable amount was extracted years ago, one excavation, near the surface, yielding as much as \$498,000. The present depth of double compartment shaft is 365 ft. Levels are opened at the 150, 250 and 350-ft. stations. Now drifting and stopping on the first and second levels—the first producing about 45 tons per day. A very fine body of ore is understood to have been struck not long since on the second level. The third level has been run 120 ft., and has yet to make about 40 ft. more before cutting the lode. The entire width of ore and ledge matter together is fully 250 ft.

The best pay ore on the 150-ft. level is from 2 to 10 ft. wide, averaging \$100 per ton. The best, if assorted, would yield as much as \$700. On this level there are hundreds, if not thousands of tons, of lower-grade ore that can be made to pay a profit with cheaper mining and milling facilities. The company is now shipping at the rate of 60 tons per day to one of the Northern Belle mines, the result of which will probably soon be heard from.

Anticipations as to the future of the mine are at present running high. Many supposed to be well posted, are of the opinion that she is destined at no very distant day to rival, if not eclipse, her dividend-paying neighbor to which allusion has more than once been made. So mote it be.

The East Mount Diablo,

Adjoining the above, has had little development on the surface. Lying between the Mount Diablo on one hand and the Gen. Jackson on the other the character of the ground will soon be determined by the explorations now going on in these mines. The Mount Diablo on one of her levels is now within 120 ft. of the line, and said to have at this point a good strong vein.

The Gen. Jackson's Shaft

Is also within 150 ft. of the east line of the East Mount Diablo's ground, and as both properties belong to the same company, prospecting will be carried on simultaneously.

The Jackson incline shaft is now down 155 ft., following the vein.

About 35 tons of ore, looked upon as first-class have been taken out, estimated to mill \$100 per ton, and the mine is considered a fine prospect.

The Candelaria (No. 2),

South of the Gen. Jackson and East Mount Diablo, has recently struck very fair ore. Shaft, 80 ft. deep and drift on lode, 130 ft.

The Mountain Girl,

The property of Messrs. Sutherland, Murphy, and McLane, is situated due east of the Mount Diablo hoisting works. It is the first extension of the Denero or the famous Mountain Boy lode. Shaft now down 230 ft., and work rapidly pushed with two shifts.

The owners are very sanguine as to results.

The Windsor,

North of the Jackson, some years ago extracted ore that milled as high as \$300 per ton. Very good ore is said to have been found at the depth of 160 ft., the shaft on the way down, cutting veins from 8 to 10 inches wide, the ore giving assays from \$20 up to \$300 per ton.

The Saratoga,

Near the Windsor, is at present taking out ore worth \$300 per ton, assay value. Preparations are making to erect machinery.

The Eastern Belle,

Running parallel with the Windsor, has a shaft 150 ft., a north drift 150 ft., and one south 170 ft., both through vein matter, but neither cutting the lode. An incline on the vein struck ore at the depth of 50 ft., that assays from \$20 to \$40.

The New England,

Some distance further east, comprises several claims, being 1,500 ft. long by 1,400 ft. wide. It has been opened by shaft 120 ft., by incline, tunnel, winze and drifts, developing ore bodies in different parts of the claim. The ore, as to character, is classed as chloride and manganese. About \$6,000 worth was extracted at one point, working from \$250 to \$300 per ton. The mine is now being worked through a shaft and incline aggregating a depth of 130 ft., from which level an east drift has cut a body of ore, the extent and value of which are not yet known, two assays going respectively \$113 and \$212 per ton.

On the Columbus side of the mountain, W. J. Sutherland, Esq., has recently had some claims incorporated under the name of

The Highland Chief.

The ore is represented to be rich and the prospects unusually flattering.

The Tilden,

One mile from the town of Columbus, was discovered as early as 1869, and yielded soon after a very considerable amount of bullion. It lies in the granite, and the rock is understood to be more than ordinarily rich. It has been relocated, and the work is expected to be vigorously prosecuted. On account of the water to be banded, hoisting works will be required.

Having now given a brief sketch of most of the principal mines of this great mineralized zone, it may be well to give some account of

The Two Great Drawbacks

To successful operations in the district, more particularly at the west end. Wood and water are both scarce and dear. Water sells at from 5 to 6 cents per gallon—is hauled from Belleville and Columbus, the distance of from 8 to 10 miles. When it is remembered that there are thousands upon thousands of tons of low-grade ore here, which could be made to pay with mills on the ground and cheap power for hoisting purposes, the magnitude of these drawbacks must be at once apparent.

Proposed Remedy.

It is understood that a franchise has been granted to a company to supply Candelaria with water. The source of supply is from springs about 10 miles distant. The company claims to be able to furnish 15 times the amount now used—a sufficiency not only for family use, but for all milling and mining purposes. The water has been tapped by a tunnel 1,000 ft. in length. The estimated cost is put somewhere from \$40,000 to \$50,000. It is understood, also, that an abundant supply of water can be obtained from another source, if needed. It will cost something more, the distance being greater. Scarcity of wood will be remedied as soon as the narrow-gauge railroad reaches Candelaria, and much of the ore can be shipped to Carson river or other points to be worked, if a sufficient number of mills are not in the meantime constructed for the purpose on the ground.

A. C. K.

MOUNT GRANT.—All that region of mountainous country, on and about Mt. Grant, Esmeralda county, Nev., bears the same name as the mountain peak, and still there is a vast difference in the mineral character of the country within the space of a very few miles. For instance, on and about Mt. Grant proper, as well as about Squaw creek, a short distance from it, all the gold and silver-bearing ores are more or less mixed with base metals, while between the two lies a belt of free gold ore. On this middle belt, six miles south of the foot of Walker lake, and seven miles south of the proposed town of Milbrae, which is to be the shipping point for Bodie from the Carson and Colorado railroad, is located the Golden Eagle mine, owned, in part, by Bodieites, and near this is the somewhat famous Big Indian mine, both containing large quantities of free gold ore of high grade. The Big Indian people have sent to the Comstock to purchase a mill, having an abundance of ore in sight. The Golden Eagle has also a large quantity of high-grade ore in sight, and several other claims on the "free belt" have fine prospects.—*Bodie Standard-News.*

Northern Esmeralda.

Revival of Operations in Old Camps.

A representative of the *Bodie Free Press* spent last week in the northern portion of Esmeralda county, Nevada, about 50 miles north of Bodie, and about 60 miles south of Virginia City, visiting Cambridge, Rockland, Pine Grove and other points.

The most extensive mining operations now in progress in northern Esmeralda are at Cambridge, at which point is situated two or three series of ledges and a 10-stamp mill. Most of the mines and the mill are the property of ex-Gov. H. G. Blasdel, and are under the immediate personal supervision of Col. S. W. Blasdel. The mines are located in a low range of granite hills, running northerly and southerly, which rise up from the plain between the range of mountains in which is situated Pine Grove and Rockland to the west, and the range of which Mount Grant is the principal peak to the east. The Cambridge mines have been worked to some extent for 15 or 20 years past, their discovery dating prior to that of the Comstock lode. Numerous shafts have been sunk to a depth of from 100 to 150 ft., and the Wheeler Bros., who owned largely in the district years ago, when it was known as the Salt River district, erected a small mill on the banks of the East Walker river and worked the ores with more or less success. The ores are, except those taken from the Blackhorse mine, low grade and somewhat difficult to treat successfully. They contain copper, galena and iron in carbonate and other forms. In the precious metals gold largely predominates over silver.

A little over a year ago Gov. Blasdel purchased the mines, which comprised the Williams, Blasdel, Walker River, Black Horse and El Dorado, together with a ranch of bottom land on Walker river, about a mile distant from the mines. He replaced the old Wheeler affair with a 10-stamp mill of the modern sort, fully appointed with all the latest appliances, and a model of convenience and economy in working. It is run by water power, supplied by a large race from the Walker river, about three-quarters of a mile in length, from which, also, water is supplied to irrigate the ranch. In connection with the mill are two large boilers, used merely to supply steam for the pans, an office, assay office, retort room and manager's residence.

The mines are on three parallel ledges, about 1,000 or 1,500 ft. apart, and are each 600x1,500 ft. Each of the ledges shows separate and distinct characteristics, the Williams ledge showing the greatest tendency to shaleness, and the Black Horse being the nearest free milling. The latter vein contains very rich ore, which is found in successive kidney-shaped chimneys. Its color is usually a reddish brown, and free gold can be seen on nearly every piece. The ledges are traceable on the surface for a mile, or even a greater distance. The granite formation is of a highly silicious character, and is filled with mica. The mines are easily worked, and there being a steady grade thence to the mill, ore is transported for reduction at a very light expense. The mill was completed last year, hut, with the exception of a few experimental runs, has not been put to work regularly until this season. Some difficulty has been experienced in securing the services of an amalgamator competent to work the ores, containing as they do bases of various kinds. Dr. Matthews, who has a very extensive fund of scientific knowledge, is now attending to this work, and is meeting with considerable success.

The Virginia and Bodie line of stages runs up to the Cambridge postoffice, which is in charge of Wells, Fargo & Co.'s office, which is in charge of Capt. J. H. Williams, as postmaster and express agent. Capt. Williams owns a mine known as the Reese; Capt. Williams and E. R. Willis the Willis mine, and E. R. Willis the Summit.

The situation of the mill and ranch is very pleasant to the eye. Shut in on every side with low granite hills, the mountains further away forming a dark background, the willow-banked river running through the green meadows impart to the place the character of an oasis in the desert. It is 2,000 or 3,000 ft. lower than Bodie, and the climate is correspondingly mild, snow in the winter time seldom remaining on the ground more than an hour or two. Altogether Cambridge, while being a peculiarly pleasant place of residence, gives promise of becoming a profitable bullion-producing region.

Rockland.

About eight miles to the west of Cambridge, in the same range of mountains in which is situated Pine Grove, is Rockland, a camp which years ago was a lively one, as its little graveyard, in which 8 or 10 were buried with their boots on, fully attests. The principal mine in this district is the Dolores, from which has been produced about \$200,000. This mine was purchased by Gov. Blasdel four or five years ago, and a 10-stamp mill was erected by him. The fact that no snow fell for two or three years, caused such a drought that sufficient water could not be obtained to run the mill. As a consequence, operations have been almost suspended in the district since that time, with the exception, perhaps, of a little prospecting. Work has been resumed on the Dolores mine this summer, and Col. Blasdel has taken out some ore and shipped it to the Cambridge mill for reduction. The mine has been developed by six different tunnels in the mountain about 100 ft. apart, all of which, except the last, was run on the ledge. The last was run in at right angles with the ledge, and intersected it at a distance from its mouth of about 750 ft. The

two tunnels above the lower one are each about 1,000 ft. in length. The ore is found in chutes in the fissure, which is continuous throughout, these being 100 or 150 ft. in length, and from 2 to 12 or 15 ft. in width. Immense chambers have been stope out in the mine on different levels, but there is still in sight an immense showing of ore. The ore produces gold and silver, which is found principally in sulphurets, and runs from \$20 to \$150 per ton. Specimens of rich rock from the lower tunnel have assayed as high as \$1,500. The ledge runs nearly north and south, and pitches east, and, as it is plainly indicated on the lower tunnel, is a contact vein, the east rock being a sort of quartzite and the west a porphyry.

Ex-Senator A. Garrard owns an extension of the Dolores, which has been developed to some extent by a tunnel, from which some very rich rock has been taken.

The only appearance of life about Rockland now, is the small force of men at work in the Dolores. The houses in the once busy little town are all deserted—the express office, post-office, saloons, stores and residences—and the open doors swinging on their rusty hinges give out a most doleful and ghostly threnody.

Pine Grove.

North of Rockland three or four miles is Pine Grove, which has a record of bullion production of a million and a half of dollars. Here are situated two 10-stamp mills, one of which is now at work. The principal mines are the Wilson and Wheeler—the former being the only one in which anything is doing at present. The Wilson has a tunnel about 1,500 ft. in length, and is owned by David Wilson & Sons. The tunnel is but 200 or 250 ft. below the surface at any point. Sixty ft. below this tunnel, however, another tunnel is being run. The ore in this mine is found in successive chambers. The ledge formation is very wide, the veins of ore usually being found about four ft. in width, on the hanging wall. The mine is worked on the tribute system—that is, the miners pay a certain fixed price for working the ore, and the owners receive a proportion of the profits above the cost of milling. The Wheeler has been a large producer, but at present work is suspended on that property. The town of Pine Grove appears to be a thriving little community. No whisky is allowed to be sold in the place. All work is suspended on Sunday, and but for the isolation from the main routes of travel, it might be a very pleasant place to live.

There are several other districts of more or less importance in northern Esmeralda—including Washington district and Mount Grant, and the prospects for extensive operations in that section at no distant day are remarkably good.

Belmont and Adjoining Districts.

It would be a good thing, says the *Belmont Courier*, if the owners of closed down mines in this and adjoining districts would dispose of them to parties who are willing to develop them in a thorough manner. It has been the custom in this country to coyote under the grass roots, and after working out the ore above water level, close down for an indefinite period. Tybo (at one time one of the liveliest bullion-producing camps in Nevada) is under a cloud just now from this ruinous system of working, and Tybo has as good mines as any in the country if the company will only develop them properly. Belmont is pretty much in the same fix. There is only one company working at present—the Belmont. Work in this mine is progressing satisfactorily and a good quantity of fair ore is being extracted from the stopes. The concentrating mill will soon be ready to start operations. Depth is necessary to develop the mines, both here and in Tybo, and to attain this a large shaft must be sunk and heavy machinery put up. Jefferson is almost as quiet as a graveyard from the effects of mismanagement, and yet there are mines there that ought to be paying handsome dividends instead of being shut down. Ophir canyon is in the same fix as Jefferson, and yet before the fault occurred in the ledge, hundreds of thousands of dollars were taken out of the mines there. At Grantsville the mines are being opened in a thorough and systematic manner, just as mines always should be opened. The Alexander company will soon have 40 stamps pounding away on ore from this celebrated mine, and there is enough of it already exposed to keep this mill running for the balance of our natural lives. The Brooklyn company is erecting hoisting works on its valuable property, and it is the intention to sink a shaft and thoroughly develop the mine. These mines have never been assessed. The mines at Morey are being worked in a satisfactory manner with flattering results. The Barcelona mine at Spanish held is opening up splendidly and promises to develop into one of the highest mines in eastern Nevada. In Philadelphia district if two or three companies will unite and sink a combination shaft they will undoubtedly open up bodies of ore that will make handsome returns to the stockholders for the outlay. Mining men of acknowledged ability are satisfied that the mines of this district can be profitably worked to a great depth.

FANCHER'S AMALGAMATOR.—O. P. Powers, one of the largest mine owners in Butte county, has purchased the right to use Fancher's amalgamator on any mining ground that he has. He made the purchase after having given it a thorough trial and finding that it would do just what its inventor claimed that it would do.—*Oroville Mercury.*

MECHANICAL PROGRESS.

WELDING BY PRESSURE.—Mr. Spring still continues his researches on welding by pressure. He has already submitted more than 80 solid pulverized bodies to pressures ranging as high as 150,000 pounds per square inch at various temperatures. The results, which have an important bearing upon geology and mineralogy, are of considerable interest. He has found that all crystalline bodies proved capable of welding, and in the case of bodies accidentally amorphous the compressed block showed crystalline fracture—crystallization had been brought about by pressure. Softness favors the approximation of the particles and their tendency to their placing themselves in the direction of the axes of crystallization. The amorphous bodies, properly so called, fall into two groups, ones of substance like wax, which weld easily, and the other of substances like amorphous carbon, which do not weld. The general result is that the crystalline state favors the union of solid bodies, but the amorphous state does not always hinder it. Prismatic sulphur is changed by compression to octahedric sulphur; amorphous phosphorus seems to be changed to metallic, and other amorphous bodies change their state. In all cases the body is changed into a denser variety, whence may be inferred that the state taken by matter is in relation to the volume it is obliged to occupy under action of external forces.

A NEW SCREW.—It is a well-known fact that the great bulk of the screws used are driven in with the hammer, and given a turn or two with a screw-driver, to bring them flush. Recognizing this fact, an ingenious inventor for many years somewhat prominently identified with the business, has brought out a new screw, which is adapted for driving, and which enters the wood without tearing the grain. The gimlet point is dispensed with, and a cone point substituted. The thread has such a pitch that it drives in barb fashion, offering no resistance in entering, but firmly resisting all attempts to withdraw it except by turning it out with the screw-driver. The head is flat, but in setting it up two nipples, or square shouldered projections, are raised in it by the one operation. The screw-driver takes hold of them more easily than it does of the customary nick, and holds quite as firmly, and when driven flush the projections on the head are not in the way, and do not disfigure it. It is claimed that this screw can be made one-third cheaper than ordinary screws, the principal saving being effected in the doing away with the necessity of sawing the nick in the head.—*Design and Work.*

PUDDLING OF IRON.—Mr. E. Harris, the President of the South Staffordshire Mill and Forge Masters' Association, in a paper which he has just read before the institute on the puddling of iron, said that the schemes tried to prevent smoke, save fuel, etc., might be counted by scores, but none of the recipes had been so effectual as to secure a general adoption. It was a mistaken theory to suppose that because iron was fibrous in the puddled bar it would be fibrous in the finished bar. Often enough the puddled bar was crystallized, and no matter how many times this class of iron was worked over again, fibers could not be developed. The "hot short" iron was as much to be guarded against as the "cold short," for whilst the engineer in constructing a bridge or building a vessel dreaded the "cold short" iron, the blacksmith and the boiler-maker equally feared the "hot short."

The use of blowers under steam boilers is being gradually abandoned. The disadvantages are numerous. It requires a larger amount of power to run them, and unless the mill is situated away from other buildings causes great annoyance and danger from sparks and cinders. A planing mill at the South End, Boston, was set on fire five times in as many years by sparks. Another mill was set on fire, caused by back draft into the boiler-room. The action of the blast on the crown sheet of boilers is like a blow-pipe, always striking in the same spot, and it is safe to say boilers will last double the time running by natural draft. A mill near Boston started with blowers under six new boilers, and had to renew the crown sheets within two years' time.

SIZE OF GOVERNOR PULLEYS.—The *Manufacturer and Builder* gives the following rule for fixing the size of governor pulleys: To find the diameter of the governor shaft pulley, multiply the number of revolutions of the engine by the diameter of the engine shaft pulley, and divide the product by the number of revolutions of the governor. To find the diameter of the engine shaft pulley, multiply the number of revolutions of the governor by the diameter of the governor shaft pulley, and divide the product by the number of revolutions of the engine.

A REMARKABLE CASTING.—The most novel exhibit shown at the Brussels national exhibition by the Sraing works is a certainly remarkable casting. It consists of what is practically the whole cast-iron work of a marine engine, with a pair of cylinders about 20 inches in diameter by 20 inches stroke, cast in one piece—head-plate, condenser, air and feed and bilge pumps, standards, cylinders and exhaust pipe.

HOT POLISHED SHAFTING.—Since the early part of 1876 the Akron Iron Co., of Ohio, have given much attention to the manufacture of hot polished shafting by a process which, while it yields a product possessing important advantages, is such that only the best raw material can be employed. This fact is in itself a guarantee against any inferiority in the shafting turned out, and has contributed to its growing popularity with the manufacturers of agricultural implements, in the construction of which light—and, therefore, strong—parts are eminently a necessary factor. The process of the manufacture of hot polished shafting affords special facilities for turning out true work, and for making it to the gauge desired without having recourse to the lathe. A circumstance which makes the product of the improved process particularly suitable for line and counter shafting, is that it does not spring or warp in key seating. The well-known effect of polishing iron at an elevated temperature—that which gives Russia sheet iron its peculiar blue finish—is produced by the process adopted in this case. A magnetic oxide, adhering firmly, is superficially formed, affording protection against the formation of rust. We have had occasion to examine specimens of the shafting referred to, which show in a characteristic manner the presence of the coating thus obtained, and which, in conjunction with the other peculiarities noticed, render it worthy of the attention of those interested.

DIFFICULT CASTINGS.—The Ames Manufacturing Company of Chicopee are making some of the most difficult iron castings ever attempted in this country, in the shape of engine tube for the Seymour Paper Company of Windsor Locks, Conn. One was made a few weeks ago, and a second has just been turned out, both jobs being accomplished without accident. The tube is nineteen ft. long, eight and a half ft. wide, and thirty-two inches deep, the sides and bottom averaging about seven-eighths of an inch thick. They have heretofore been made in four pieces and riveted together, as it was thought impossible to make the whole in one casting. Many old molders, hearing that the work was to be undertaken, prophesied a failure, and iron-workers from as far off as Pittsburg, Penn., came to see the first cast. The Seymour Company are to have several more made, believing that though they cost a good deal to make and to handle, they will last, when once in place, as long as the mill stands. The Ames Company are to be congratulated on their success, as the work was very difficult. Eight tons of metal had to be melted for each tub, and a weight of 45 tons was piled upon the cope or covering to hold it down when the iron was poured into the big mold.—*Paper World.*

RENDERING IRON FIRE PROOF.—Iron, as is well known, is in some respects the very best material that can enter into the construction of a building, and in other respects it is the worst; of the latter phase we would speak. It is hardly necessary to refer to the fact that iron pillars and joists are very susceptible to the influence of heat, and that a fire of small magnitude will soon warp and twist them to such an extent that the fall of the whole structure becomes a certainty. Iron will endure pressure and strain under ordinary circumstances, but will quickly succumb to the influence of heat. To guard against this and to place it in the front rank of materials used in construction, it is proposed, with reason, too, that in all buildings in which iron is a factor, that it be encased in some non-conductor of heat. Terra-cotta has been suggested as the remedy. It may detract from the appearance, but that should be subsidiary to safety. If iron can be rendered a salamander it is certain to rise in favor, because it possesses all the other desirable properties required in the construction of buildings—lightness, strength and beauty.—*Insurance World.*

SHOULD SAND BE USED IN WELDING?—A correspondent of the *Blacksmith and Wheelwright*, writing from Glen Falls, N. Y., says: "The rule among smiths generally seems to be that the more sand they can get on in welding the better, the idea being that the iron will be heated more evenly by this process. Some time ago I got out of sand and could get no more for a time. After I had worked a while without it I did not want any more, and have not used it since. Some of the reasons for not using it I will name. The forging is cleaner, and it takes less time to do work without than with sand. I have done just as good work since I stopped using it as before, and have done it in less time. I would like the opinion of the trade on this subject. If it can be shown that there are reasons for using sand which will more than balance the reasons for not using it, I shall be glad to know them. The sand used by smiths here is from molders' castings."

NOTES ON STEEL.—Steel merely hardest is hardened on the surface, while in steel that has been tempered the exterior is the softest. In the one case because the surface was cooled in advance, in the other because it was heated in advance. Steel which has rusted can be cleaned by brushing with a paste composed of ½ oz. cyanide potassium, ½ oz. castile soap, 1 oz. whiting, and water sufficient to form a paste. The steel should first be washed with a solution of ½ oz. cyanide potassium in 2 ozs. water.

SCIENTIFIC PROGRESS.

Gould's Comet.

Prof. Klinkorfues, of Göttingen, has published a letter on Gould's comet, discovered last February at Cordova. His object is to point out that the probable identity of this comet with those seen in 1843 and 1868 need not be rejected because it does not appear to have been seen, although so conspicuous an object between those years. So nearly does it approach the sun (within, indeed, about 100,000 miles of its surface) that the resistance to its motion when at perihelion is likely to be sufficient to produce a very considerable diminution in its periodic time, the case being, in fact, one of resistance from the sun's atmosphere itself, and not merely, as has been conjectured in the case of Encke's comet, from the ethereal medium existing in space. Hence there is nothing extravagant in the supposition that the resistance of the part of the corona within which the comet passes may be quite sufficient to diminish its period of revolution from 175 years to 37 years. Carrying this view still further back, Prof. Klinkorfues contends that it is probable that the same comet may be identical with one seen and described by Aristotle in the year B. C. 371, when that philosopher was only 13 years old and still living in his birth-place, Stagira. He considered it likely that while the period of revolution from B. C. 371 to A. D. 1668 was 2,039 years, it was diminished by the resistance of the sun's atmosphere, first to 175 and then to 37 years; and, further, that it has at the late passages through perihelion been again decreased to 17 years, so that it may be expected that the comet will return in the autumn of 1897.

MALLEABLE NICKEL.—Dr. A. Fleitmann, of Iserlohn, Germany, writing to a German scientific paper, gives the most detailed account yet published in regard to his well-known method of making malleable nickel and cobalt by the addition of magnesium. Herr Fleitmann has found that nickel containing zinc is, to a certain degree, malleable, and that such an alloy can be rendered malleable by smaller proportions of magnesium. In order to make the nickel zinc alloy, the pure oxide of nickel is very thoroughly mixed with 5% of oxide of zinc, the whole being reduced to metal which contains about 4% to 5% of zinc. The presence of zinc is said to act upon the nickel in a remarkable manner, a malleable metal being produced, even without the addition of magnesium. It is likely that the brittleness of melted nickel is due to the presence of some cyanogen, and that both magnesium and cyanogen act by forming volatile cyanides, and possibly by decomposing any carbonic oxide present. After the addition of 1-20th % of magnesium, the nickel zinc alloy is claimed to become completely malleable, and to be capable of being welded both to nickel and to iron or steel. Messrs. Fleitmann & Witte have rolled sheet nickel two ft. wide and have turned out nickel-plated sheet-iron or steel. Thicker plates of nickel are welded to the iron or steel plates, heated to a high temperature, and are rolled out together in the ordinary way without scaling off. It should be noted that steel sheets thus nickel-plated cannot be hardened. The nickel-plated sheets are said to take a fine polish.

THE NEW PHOTOPHONE.—The editor of *Popular Science Monthly*, in alluding to Mr. Bell's new instrument, the photophone, says: "Though it is said that light produces the effect, yet this is not strictly true; for a thick plate of India-rubber, if interposed in the path of the acting beam, intercepts all the light but still permits the passage of the radiant force which produces the sound. It is some dark ray accompanying the light proper that does the work. The experimenters have found also that other substances share with selenium the property here made available, though in a less degree. We thus have another step in the rapid progress of molecular physics and the marvelous interaction of forces which is sure to stimulate experimental inquiry, though whether it will confound past conclusions and clear up past mysteries it is impossible to say. And equally impossible it is to say whether the photophone will turn out to be of any practical use. But it is certainly unsafe to deny it. The telephone is but a thing of yesterday, and was at first supposed to be only a curious plaything. But already 'there's millions in it.' How far it is developed as a business is shown by the fact that a convention of 21 companies meets at Niagara to look after the interests of this new and rapidly extending means of intercommunication."

THE COURSE OF A LIGHTNING FLASH.—Prof. Tait, of Edinburgh, insists that when people think they see a lightning flash go upward or downward they must be mistaken. The duration of a lightning flash is less than the millionth part of a second, and the eye cannot possibly follow movements of such extraordinary rapidity. The origin of the mistake seems, he says, to be a subjective one, viz., that the central parts of the retina are more sensitive, by practice, than the rest, and therefore that the portion of the flash which is seen directly affects the brain sooner than the rest. Hence a spectator looking towards either end of a flash very naturally fancies that end to be its starting point.

Salt Lake in Ancient Times.

It is well known that the ancient water surface of the great Salt lake of Utah once covered a vast area of country, probably more than ten times that covered by the lake at the present time. The most conspicuous vestiges of that great body of water are found in its extensive shore lines, which are, even to this day, most unmistakable in their character. It is also known by these indications that the surface of the lake was at one time fully 1,000 ft. above its present level. The lake at that early period most undoubtedly had an outlet to the ocean, and much speculation and no little research has been indulged in to fix upon the locality of this outlet, but as yet without any generally satisfactory result. The *Popular Science Monthly* sums up the results thus far as follows:

Mr. G. K. Gilbert maintained, in the *American Journal of Science* for April, 1878, that the point of overflow was Red Rock pass, Idaho, at the north end of Cache valley; that the discharging stream descended through Marsh valley, and thence continuously to the Pacific ocean; and that, flowing over soft material at first, it gradually excavated at the pass a channel more than 300 ft. deep, and lowered the level of the lake by the same amount.

Dr. A. C. Peale controverted Mr. Gilbert's conclusion in a subsequent number of the *Journal*, and held that the original altitude of the Red Rock pass was considerably below the highest level of Lake Bonnaville; that the original shore line exists in Marsh valley, at the north end of the pass, as it does in Cache valley at the south; and that the real point of discharge, when the water stood at the Bonneville level, was about 45 miles north of Red Rock pass. Mr. Gilbert has, within a few months, revisited Marsh valley and Red Rock pass, and other points near the former supposed outlet of the lake, and gives in the May number of the *Journal* his reasons, derived from his later observations, for adhering to his former conclusions.

He assumes to determine the character of the body of water which has occupied a given spot, whether it was a stream or a lake, from the nature of the terraces left in the valley. Thus there are stream-terraces, and wave-terraces, and delta-terraces, and others, all marked by distinct features. A lake should leave wave-terraces or delta-terraces. In revisiting Marsh valley, he traversed it from end to end, making a careful search for the terraces of the ancient shores, selecting the most favorable stations and lights he could get. He saw stream terraces and displacement-terraces of considerable magnitude, and a few inconspicuous terraces due to unequal erosion, but no wave-terraces and no delta-terraces. He made a special examination of two terraces referred to by Dr. Peale in support to his views, but did not recognize in them any features inconsistent with the opinion that they are stream-terraces. He consents to reconsider his original location of the outlet of the lake at the time of the beginning of the overflow, and assigns it to a position two miles north of Red Rock.

Mr. Gilbert Thompson, an expert topographer, visited the northern limits of the lake in 1877, while ignorant of the results of Mr. Gilbert's examination, and came to the same conclusion that he had reached.

A CURIOUS FACT has been brought out by the examination of the artificial diamonds obtained by Mr. Hannay, to the effect that nitrogen was present in chemical combination with the carbon. Mr. Hannay is inclined, therefore, to believe that his diamonds were formed by the decomposition of a nitrogenous body, and not by the decomposition of the hydro-carbon. The diamonds, moreover, were not found when nitrogen was absent; but the successful experiments are still too few, and the evidence too vague, to justify drawing any conclusions on this subject.

A NEW SHADE FOR ELECTRIC LIGHTS.—A French inventor, M. Clemandot, has devised a shade for reducing the glare of electric lights, which he claims to be much more economical than ground glass globes. He makes his lantern of glass tubes filled with finely spun glass threads or glass wool. By reflection from the glass threads the light is given the desired diffusion, with a loss of illuminating power not exceeding 15%, against 30% or 40% with opal or ground glass. The natural blueness of the electric light can be corrected by tinting the glass tubes or the inclosed wool.

An improved method of stopping engines, says the *Electrician*, has recently been devised. The main object of the device is to enable any child or unskilled persons in any part of a mill to stop the engine in case of accident. The action is exceedingly simple. By touching a spring similar to the spring of an electric bell, an electric hall is set in motion. The hall drops and shuts one of the valves, which prevents the steam from escaping, and the engine is brought to a stand-still.

PHOSPHORESCENT LIGHTNING.—Dr. Phipson takes sulphide of barium, or some other substance which is rendered phosphorescent by the solar rays, and includes it in a Giessler tube, through which he passes a constant electric current of a feeble but regular intensity. He claims to obtain in this manner a uniform and agreeable light, at a cost lower than that of gas.—*Les Mondes.*

MINING SUMMARY.

The Custer has 7 men at work, with a big dump of ore out and "plenty in sight." Other properties are at work with stronger forces, so that "base bullion from Inyo" will again be in order, especially as the Modock furnace is expected to start up about the same time.

require roasting, and the company being now assured of a successful mode of treatment, will erect the necessary works. This mine is improving as depth is gained. The vein is over 50 ft in width, and the pay streak is widest on the lowest levels.

ADDENDA.—It will be recollected that this mine, which runs north and south along the summit of Silver Hill, was projected to a depth of 400 ft through an incline shaft. Three levels were run from the incline, at depths respectively of 300, 350 and 400 ft. There was such marked improvement on each successive level that the company determined to sink a new vertical shaft of sufficient size and proper pattern for working to great depths. The new shaft was started about the commencement of the present year, or a little earlier. It is now 520 ft in depth, and 2 levels have been run from it at 400 and 500 ft respectively. The shaft is a 3-compartment, timbered from top to bottom with 10x10 square sets.

NEVADA.

PAY GRAVEL.—*Fort-Hill Tidings*, Oct. 8: It is reported that a cave in the Wind-Up mine, near Quaker Hill, revealed to the workmen good gravel below the tunnel.

RICH ROCK CONTINUES to be found in the Ford & Muller claim, as also in Rocky Bar.

PROGRESS AT THE PROVIDENCE.—*Nevada Transcript*, Oct. 10: The hauling works being built at the Providence mine, to take the place of the ones recently destroyed by fire, will not be completed for several days yet. The stous masons finished their part of the work yesterday, and it is expected the pump will be ready to start by next Saturday. The remainder of the machinery and the building will be put up as quickly as a large force of men can accomplish the job.

YOE BERT has it is understood that Judge Brown and his brother will make a contract with the South Yuba company soon for water with which to work their claim this winter. Should they conclude to begin washing, it will necessitate the digging of a ditch. The water would probably be conveyed across Steep Hollow by means of pipes hung to a suspension bridge. The Birdseye Creek company, who make a large clean-up a couple of weeks after the wash, are still washing. They will quit soon in order to fit up for next season's work. Some Chinese yesterday brought to the city and sold amalgam amounting to considerably over \$1,000, which they say came from a small placer claim in the vicinity of Yoe Bet.

PLACER.

GLITTERING WITH GOLD.—*Placer Herald*, Oct. 6: We mentioned last week that Roberts & Roberts, of the Central level, on Duncan Hill, were taking out some good rock. We were unaware at the time just how good it was. On Monday we were shown some samples of the ore then being extracted that astonished us. They fairly glittered with the filthy lute, and aside from the liberal showing of free gold, the general appearance of the rock was decidedly fine.

RATLESNAKE BAR.—Both river and quartz mining are busily operating here. Bates & McNeill are doing well. Mr. Zintgraf has found a new ledge larger than the original location, and quite as good. Craig & Fullerton's claim has not yet made a showing, but they have good ground, and will probably be heard from ere long.

PLUMAS.

TRAMWAY.—*Greenville Bulletin*, Oct. 6: The Green Mountain Co. are building a fine tramway from tunnel No. 5 to the new mill, a distance of a quarter of a mile. It will be so arranged that the loaded cars descending will draw the empty ones back to the tunnel.

NEW WANTED.—Quite a number of good miners could get work here now, and if any of our mining exchanges know of miners desiring work, please send them the way. A few carpenters could also find employment here at present.

DUMP HOUSE.—The Choreskes Co. has recently built one of the best dump houses in the mines. It is 35x40 ft, capacity, 800 tons of ore. There are 12 chutes leading to a wagon road in the middle, and the cars run from the tunnel without the loss of a wheel.

BIO PAY.—*Plumas National*, Oct. 9: Mr. J. H. Loring showed us some slugs the other day, which he got in his last week's work in the Loring & Leavitt claims, at Elizabethtown. They were big old-fashioned nuggets, weighing about \$30 each. Three hundred dollars were taken out from two sets of timbers. After 6 years of hard labor in getting this "hounza." It is a pleasure to chronicle their good luck. Since obtaining the nuggets, the men have some further rich developments in the shape of 25 ounces to "one pick," on Wednesday. They are certain they have got the "old Emigrant Hill lead," and there is no use in being surprised at anything they may get. And this is one of the "played out" Plumas mines.

ANOTHER STRIKE.—We are informed that another rich strike has been made in the tunnel claims owned by Alf Smith and the Cox, Davis estate, near Buttery, or rather at the head of Eliza's fork. Some time before Davis' death, Cox, Leo and Doc, Garrett leased his half of the mine, and they have been running tunnels ever since. Lately they have been making big wages, some reports say \$30 a day to the man. We are glad to hear of their good fortune, and hope that this boys will get "a hoot box full" before they lose the lead.

GOOD GRAVEL.—Mr. R. Z. Bell has lately been at work reaping and getting in order the Western gravel claims, near Newton. They have just got to work in the gravel, and for "a starter" took out \$23 to 2 picks on Wednesday. The Plumas gravel mines are "booming," sure enough.

ITEMS.—Two dollars and a half to the pan a day or two more in the big shift at Jamison, no more rock yet. That channel is known to be 14 miles long, and never has a pick stuck in the bottom of it. Every visitor to the Monte Christo mine brings additional evidence of its wonderful riches. Blue gravel and "lousy" with gold. The Black Hawk and Butt rily country is commencing to show up some big prospects.

SIERRA.

STEAM DRILL.—*Mountain Messenger*, Oct. 9: The Ruby company are preparing to put a steam drill at work in their tunnel at Cariboo ravine. Portions of the drill are lying at the Pileocene mine. The balance of the machinery is expected to arrive soon. The company are building a "tail" from Ruby Creek around into the ravine over which to take material.

BLACK JACK.—A winze has been sunk at the Black Jack and quartz found that pays \$24 to the ton, besides a large amount of sulphurets for which there is no way of working. When Supt. Welch returns from below, a tunnel will be started that will tap the ledge in about 100 ft.

The Bald Mountain extension tunnel will be in 2,000 ft by the middle of next week. The bedrock continues soft, and 3 ft of tunnel each three shifts of 24 hours is easily made.

EXCOBACINO.—Savage Co. are making rapid progress, better than ever before. They have struck plate rock on the left side of the face, which is considered a sure indication of a near approach to a rich gold channel.

PLUMBAGO.—Parties will be up this week to reorganize affairs concerning the Plumbago quartz ledge at Minnesota, and the prospect is work will be commenced soon again. It is deemed by Raymond & Earl, the San Francisco owners, to be a valuable property.

ACCIDENT.—An accident occurred in the Bald Mountain mine Sunday morning, by a carman running into the iron doors with a loaded car. These doors close the tunnel several hundred ft from its mouth. The night boys, thinking all the men had gone out, closed the doors, and when the carman reached the spot he saw that the doors were closed, but could not stop the heavy car on the grade in time to avoid a collision. Three sets of timbers were knocked down, but the man was not injured.

TRINITY.

BULLYHOOP.—*Trinity Journal*, Oct. 9: This quartz mining property is to be sold by M. F. Orin, Receiver, on Saturday.

NEW RIVER.—Assessor Marshall informs us that work is getting under way on the New River ditch, and they will soon have 75 white men and 50 Chinamen at work. The material, including a huge boiler, for a good saw-mill is on the ground.

NEVADA.

WASHOE DISTRICT.

The following statements made in regard to the leading mines are dated the 9th:

CALIFORNIA.—During the past week there have been extracted 1,143 tons of ore from the 1650 level, of the assay value of \$22.10 per ton. On the 2000 level the joint Ophir east crosscut are cutting out a chamber for a winze. On the 2500 level the joint Ophir east crosscut has been extended 11 ft, and the north drift has been advanced 17 ft. On the 2500 level the south drift from the Ophir lode has been advanced 18 ft. During the week \$23,117.15 in bullion have been shipped.

SIERRA NEVADA.—On the 2300 level the incline upraise to the 1700 level has been extended 18 ft; total length, 165 ft. On the 2400 level the repairs to station at east winze will be completed to-day. The pumps and air and water pipes on the old incline have all been removed and the engine used in the same is being taken up. On the 2500 level the west crosscut to the 2400 winze has been advanced 30 ft; total, 83 ft, leaving 15 ft to go.

COS. VIRGINIA.—During the past week 881 tons of ore have been extracted from the slopes on the 1700 level, of the assay value of \$21.40 per ton. On the 2000 level the joint Best & Belcher winze has been sunk 12 ft, and the north drift has been advanced 14 ft, and No. 1 raise has been extended 10 ft. During the past week bullion to the value of \$17,168.10 has been shipped.

ORISKANY.—On the 2000 level the joint California east crosscut is being chambered out for a winze. On the 2300 level the joint California upraise has been extended 11 ft. On the 2500 level the south drift has been extended 12 ft. In the 2300 level the south drift has been connected with the Mexican east crosscut. During the week 119 tons and 1,400 pounds of ore have been extracted from the 2000 level.

UNION CONSOLIDATED.—On the 2500 level the south drift from the Union shaft has been extended 30 ft. In the south drift from No. 1 winze are cutting down the grade. East crosscut No. 1 has been extended 24 ft, and crosscut No. 2 has been extended 25 ft. The upraise from the northeast drift has been extended 15 ft and the west drift hole has been extended 140 ft.

ALTA.—Since last report No. 1 crosscut has been advanced 48 ft; total length, 120 ft. The face is in soft porphyry, carrying streaks of quartz. No. 2 crosscut was advanced 47 ft; total length, 110 ft. The face is in a formation similar to that in crosscut No. 1. No water in either.

BENTON.—During the last week No. 1 crosscut was extended 45 ft; total length, 100 ft. We got through the hard rock mentioned in my last report, and now are in soft porphyry that works well. No sign of water in the face.

HALE AND NORCROSS.—On the 2400 level the south drift is being graded down. New guides are being placed in the south compartment of the vertical shaft. The mine is gradually cooling off.

MEXICAN.—On the 1000 level are resuming the north lead drift. On the 2500 level are cutting down the grade in the main north lateral drift.

C. AND C. SHARP.—The tank station at the 2400 level is being timbered up.

BRISTOL DISTRICT.

HILLSIDE.—*Pioche Record*, Oct. 6: Aulporant development is being made in the Hillside, where, on the 5th level east, the face of the drift upon crosscutting yesterday showed a breadth of nearly 30 ft of iron and spar, with between 6 and 3 ft of clear yellow carbonate, the extent of which cannot as yet be ascertained until the lagging and stulls are placed. The drift is now in nearly 500 ft, and the development looks more promising than anything heretofore in this mine for the past 3 months. From 7 to 10 tons of \$30 rock is being shipped to the Hillside furnaces from the Bay State, which is daily improving, showing a 4 ft vein of ore west of the shaft. A tunnel has been commenced for the better circulation of air. It is now in 20 ft, with small streaks of ore and hunches of copper in the face. The Hillside furnace is doing well, and the development outside of the mine, more bullion will be turned out during this run than for any previous run the past year.

TEMPER MINE.—Cliff Webster reports that work is being pushed on this mine. The main shaft has now attained a depth of 100 ft, and over 1,000 tons of ore is exposed to sight, ready to take out.

CHERRY CREEK DISTRICT.

STAR.—*Cor. White Pine News*, Oct. 7: The Star Co. is producing about the same amount of bullion as they have been doing for the past 3 months. The Exchange Co. has several hundred tons of first-class ore at their mill and are still hauling. Their mill is about ready to commence crushing, having to-day got up steam for the first time. The mill has been thoroughly overhauled and put in good repair, more stamps added, increasing its capacity, and in a few days more the exchange will again be a billion producing mine and make its mark upon the bullion tax assessment roll of old.

ESMERALDA DISTRICT.

AURORA COK.—*Esmeralda Herald*, Oct. 9: The tunnel is now in 135 ft, leaving about 30 ft to be accomplished to tap the ledge at a depth of 125 ft. The tunnel near the ledge is forming a good one favorable.

WORK RESUMED.—For some little time no work has been done on the Prospectus mine, for reasons only known to the parties interested. However, work was resumed on the Bladell tunnel, running for the main ledge, the first of the week, and is being pushed day and night. The outlook for this mine was never so good as at the present time.

REAL DEL MONTE.—Total depth of shaft is now 815 ft. Wednesday last, sinking in the shaft was suspended, and the drift on the 800 level started. The excavation for balance-hob on the 750 level was also commenced. As soon as these excavations are clear of the shaft sinking will be resumed and continued until the 1000 level is reached. The flow of water still keeps the pump running 7 strokes per minute.

SPLENDID ASSAYS.—Yesterday we were shown two certificates of assay made from rock taken from prominent mines in this district. The first was from a sample taken from a mine that has in sight to-day hundreds of thousands of tons of what is called here low-grade ore—from \$30 to \$40—and the assay showed close into the latter figure. The second was from a sample taken up in the hundreds, and was from a sample of ore taken from a mine that is well known and has plenty of the same rock. This latter mine will at no distant day play a most prominent part in the future of Esmeralda mining district.

EUREKA DISTRICT.

CALIFORNIA MINE.—*Eureka Sentinel*, Oct. 5: The Jackson mine is a good one and is owned by a rich, strong company, and still they are only working 8 men. There are many mines in this district, owned by Eureka business men, who employ more laborers and there is never a word said about their doings. For instance, Joe Mendes owns, or co-owns, the California mine, and he is showing the Ruby Dunderberg property, on Prospect mountain. We say "or co-owns," because one-half the property is bonded to Mr. A. S. Mandel, of New York, for \$25,000. From an employee of the mine, we learn that the main shaft is 136 ft deep; that they are at work upon two levels (the upper and lower), while one in the middle has ore, but the hoisting facilities are not sufficient to take out the ore. Only the three those worked. Twelve men were at work at this mine last week, and yesterday two more were sent up. The hoisting works consist of a whim, horse power, running buckets capable of hoisting from 500 to 1,000 lbs. In the upper level there is a body of ore 12 ft thick, and where work is being done on the lower one, the heaviest ore stands 15 ft high. The lower level was shown certificates of assay for 10th levels, and they run from \$50 to \$60 per ton. Upwards of 123 tons were shipped last August to the Richmond and Eureka furnaces, 23 tons now awaiting treatment at the latter and 30 at the former to-day, while the dumps are full.

ALBION.—*Sentinel*, Oct. 10: The Albion Co. are working 300 men in the mine. The Eureka tunnel is completed

a distance of 1,500 ft. Still in shale. Active mining operations are being carried on in the water level property. The California mine is shipping about 15 tons of ore to the Eureka Con. works daily. Assessment work has just been done on the Good Hope, adjoining the Lons Plac on the west. The Hope is looking well. Molino & Co., on the Mason City mine, are sinking a new shaft to the depth of 40 ft for the purpose of tapping the ore body.

I X L DISTRICT.

MILL.—*Silver State*, Oct. 5: Someone not long ago circulated the report among the newspapers of the State that this camp was a failure. We do not know who it was, and do not care to know him. There is no doubt but that I X L would be considerably further advanced if the work on the different locations had been expended on one or two instead of so many, but as it is, the mines are all looking good, and there seems to be no doubt among mining experts that the mines will ultimately prove among the best in the State. We now have every promise of the erection of a 10 stamp mill here within a short time, and there is sufficient ore in sight to justify the building of a mill of twice that capacity. There is no doubt that had the outside public taken the interest in this camp that is usually exhibited in new mining districts, we would have been crushing quartz and shipping bullion long ago. The men who have located and developed the place are worthy of every confidence, and deserving of every encouragement. They have pro-pected on limited means, and have worked and put their all in the mines, because they have unbought confidence in their permanence and worth.

PIOCHE DISTRICT.

BULLIONVILLE FURNACE.—*Pioche Record*, Oct. 6: W. J. Montgomery reports that every preparation is going on at Bullionville for the furnace and that in a short time work will be commenced. When once started it will take about 6 weeks to complete it. We hope to see it finished soon, as a number of our chloriders have ore on hand for shipment to whichever furnace does the best by them. The company is now erecting a stone building in Bullionville.

ARIZONA.

OLDS DISTRICT ITEMS.—*Silver Belt*, Oct. 6: Mr. Webster has struck the ledge in the Euclazette mine and crossed it. It is 20 ft from wall to wall, and carries ore of the same character as the recent strikes in the Mack Morris. It has gold in it. The Centennial Co. have purchased the new mill of the Euclazette Co. It can be put in order in a few days. The company are purchasing lumber and supplies, and commenced work last Friday. When in full operation they will employ 40 to 50 men. Knox & McNeilly have in their cabinet a nugget of weather-worn silver, weighing about 10 pounds. It was brought in a few days ago by M. Barron. They are timbering the main shaft on the Golden Eagle, and will have the hoisting works in operation in a few days. Stout, Bick & Co. have in their banking-room a piece of ore from the Mack Morris mine, weighing 75 pounds, which is remarkably rich. It is not a nugget, but a piece out of the body of the ledge. A rumor reaches us, too late to get particulars, that the old Skeleton mine, of which so much has been spoken, has been found, and is extremely rich in gold. It is said to be in the Sierra Anchas, or Broad Mountains. Things are going along smoothly at the Nugget. Judgeford from the pleased look which illuminates the faces of Mr. Chilson and the Superintendent, they must know something pleasant. Mr. P. T. Kelly is in from the Hatfield and Confidence mines. He brings us some rock, which is in the office and open to inspection. It carries gold and silver. The mines are located two miles from Skull Valley, on the Gila. W. H. Ford was in town Pioneer Saturday few days ago, and reports everything going along smoothly. The Great Republican mine is looking better than over. The shaft is 60 ft down and in good ore.

TIPTOP.—*Arizona Miner*, Oct. 8: The Tiptop mine continues to yield \$200-ore in large quantities, the mill to yield \$60,000 per month, and still we find the stock noted in San Francisco at \$5.

VALPARK.—Mr. Campbell returned home to-day from the Valparaiso mine, where he has been employed for some time assisting in the construction of the new 50-stamp mill of the Central Arizona mining company. The mill, in the opinion of Mr. Campbell, will be ready to drop stamps in about 60 days. Water, through the pipe from the Hassayampa had arrived at the mine. The company are prospecting the mine in a workmanlike manner.

DAY WASHING.—Valparaiso is doing good work in the placerias gold fields east of Walnut Grove. They work to a charm, and can be laid down here at a cost of about \$225.

CONCENTRATING.—*Arizona Sentinel*, Oct. 9: The Arizona Concentration Co. are now working 50 men, and are dry-washing from 50 to 100 tons of dirt daily. The dirt goes from \$2.50 to \$3.50 per ton. Their last clean-up of 33 tons averaged \$3.75 per ton, and one lot of 10 tons gave \$5 per ton. This company has an immense field for operation. They have machines for working 100 tons of dirt per day, and dirt enough to last for several years. They will soon have 100 machines at work, with a capacity of 8 tons to each machine.

TIPTOP.—*Phoenix Herald*, Oct. 8: The Tiptop Mining Co. has just made its shipment of bullion for the month of September. The bullion has been valued at \$14,400. As the mill did not run a full month, and is only a 10-stamp affair, their shipment speaks well for the quality of the ore.

COLORADO.

CAMP CLIFFORD.—*Register-Call*, Oct. 3: This mining camp, situated in York district, Clear Creek valley, was organized in the spring of 1879, and is proving up locations accessible by good wagon road routes. Considerable prospecting was done in an early day for gold-bearing quartz, but no veins were ever developed that yielded ore containing gold that would justify any person to work the veins with the methods then at hand for treating that class of pay. Three of the most prominent and recently discovered silver-bearing locations are the Jones, the Yellow Jacket, and the Yellow Jacket. The former has a shaft down to the depth of 22 ft and well cribbed up. The walls were fairly established when a break in the Consolidated ditch caused the mine to be filled with water. Since that time no deeper exploitation has been made, and it will not be until that enterprise has closed down for the winter. It is evident that the ditch will be permanently worked. Adjoining the Yellow Jacket are the Little Chief and the Yellow Eagle, which were discovered through crosscuts in the elide matter. The ore from the Yellow Jacket carries large quantities of native silver.

LINCOLN DISTRICT.—Above the mouth of the Hamilton gulch on the southerly slope of the mountain, many new veins in the spring of 1879 are proving up locations accessible by shafts or tunnels. Some of them show up well in mineral. A shaft has been sunk in the mouth of the Register-Call tunnel on the vein, and 4 inches of pay mineral has been uncovered. Crocker & Hume have discovered and are now opening up a discovery of silver-bearing ore in Upper Iowa district, on Fall River, which they have named the Lower Iowa district. The discovery is being made by working several lodges for capitalists living at Fall River and Idaho. Another season will witness a great rush to the mines along the slopes of the mountains on Fall River. A new era in mining is just beginning to dawn in this locality.

THE ROLLINS 10-STAMP MILL.—The 10-stamp mill of the Rollins gold and silver mining company, at Gold Dirt, which is being run by the management of Mr. George W. Barrett, is doing good work on the mill ores from the mines of that company. It was built for the purpose of testing the ores taken from several of the mines near Gold Dirt, and is proving highly successful for the experiments for which it was intended.

IDAHO.

CUSTER MILL.—*Yankee Fork Herald*, Oct. 6: Work is driving ahead on the Custer mill. It is expected that everything will be in running order by the 20th of November.

ORE.—Twenty tons of ore was knocked down at one blast on the Custer mine one day last week. Two pounds only of giant was required to do the work. From 60 to 70

tons of high-grade ore was displaced by 4 men in 10 hours. The rich streak of first-class ore in the Unknown has widened to 3 ft at the lowest workings. The Summit is showing up splendidly. Much of the quartz is studded with free gold.

THE SUGAR CRASS mines are looking better than ever. The ledges are large and full of good ore. Louis Bouvia struck a galena ledge 4 miles west of Bay Horse a few days ago. At a depth of 5 ft the vein made it 8 ft in width, and assays 110 ozs in silver.

THE BACINLOUT, 2 miles southeast of the Custer, is showing good ore, and has every promise of a true vein.

KAY & CO. are getting good pay on their placer ground at mouth of Jordan.

KINKINKIN.—Ore is coming into Clayton from the mines in the vicinity of Kinkinkin. The smelter will be ready to start in two or three weeks.

MONTANA.—A shipment of 13,500 pounds of second-class ore from the Montana was made on Wednesday last, per pack train, to the Bay Horse reduction works.

NUOORT.—A nugget weighing nearly 3 ozs was taken from Morrison's placer ground up Jordan one day this week. The lessees are making a good thing of it, and cau work the ground all winter.

DRAINED.—The tunnel on the Montezuma, next claim east of the Charles Dickens, has drained the shaft, and the work of taking out ore will begin in the course of a week or two.

THE CHARLES DICKENS arasta continues its large field of alluion. There are several thousand tons of pay-ore on the dumps, and more coming out every day.

HOISTING WORKS.—The new hoisting works on the Montana are nearly completed. The mine is now in perfect shape for the easy and rapid extraction of ore. A new opening is being made on the vein over 300 ft west of the present workings, showing a fine quality of quartz.

It has been well proven this year that Idaho has the richest quartz veins, and more of them, than any mineral country on the American continent.

CONSIDERABLE prospecting has been going on this summer in the Kinkinkin and Bay Horse sections, and some prospects have been struck.

MONTANA.

MILL DESTROYED AT DEWEY'S FLAT.—*Olemdale Atlantic*, Oct. 6: Last Wednesday night the quartz mill, owned by Gov. John A. Leggett, at Dewey's Flat, was entirely destroyed by fire. Supposed to have been the work of an incendiary. Only 5 steamships were mounted, but the capacity of the structure was 10 stamps.

ITEMS.—It is understood that an effort will be made to operate the 15-stamp mill of the Monroe Co., which has for some time been idle; and the Governor will at once proceed to erect a larger and better set of works on the ruins. The mines are showing much better than ever before, there being an abundance of ore in sight, and over 1,000 tons on the dump, which mill can do 100 ozs. There has been some 40 men at work, and it is to be hoped operations will soon resume, so as to make the detriment to the community as light as possible. Gov. Leggett's loss is reported to us at \$23,000, with insurance \$8,000. The mill was closed for the purpose of making a clean-up and, at the same time, repairing some portions of the machinery. It had done successful work for some time past.

UTAH.

BINGHAM NOTES.—*Salt Lake Tribune*, Oct. 6: Edwards struck a body of ore on the No. 2 East Yosemite and shipped 25 tons. Louis Martin is shipping ore every day from the First West extension of the Telegraph. The other mines along the line are being worked and the outlook is brighter. This week, with every reason to look for an improvement in condition of affairs throughout the old lead district. Hay M. J. Day is working 6 or 8 men on the Telegraph mine. The ground around the works is being graded off for a hoisting works and a boarding house. There are 12 men working on the Yosemite and extracting very good ore. The shaft has water in it yet and no attempts have been made to continue the work of sinking below the pyrites. The ore being shipped now is taken from the old vein, and some prospecting about the old lead vein.

SILVER REEF DISTRICT.—*Silver Reef Miner*, Oct. 2: The bullion shipments through Wells, Fargo & Co., for the month of September, aggregates the sum of \$97,712. The drifts both north and south in the Barbee & Walker mine maintain their fine appearance. The Stormont mine is making good shipments of fair grade ore. The new incline on the Leeds mine has now shafted a depth of 35 ft, and the ore is not only coming in in higher but improving in quality. From appearances, it will pay well for milling and extracting. The River Reef is attracting considerable attention, and the mines which are being worked never looked so well. The contractors working on the new Buckeye shaft were obliged to throw up the contract on account of the water. It is now being worked on day's wages.

CALIFORNIA.—*Salt Lake Tribune*, Oct. 10: Barnett & Hurd, a body of ore in the California mine, near the Poor Man, Ophir.

CUTTER.—The air in the Clipper mine, Bingham, is bad, and a lot of piping has been shipped to enable the miners to continue work on the body of 100-ounce silver ore struck there recently. There is great excitement in Frisco over the Carrie Lucille strike in Pine Oore district. The new machinery on the Jones Bonanza works is being worked. The air is beginning to strike the vein. Rich silver (milling) was struck yesterday in the lower tunnel of the Silver Crown mine, Black Jack, Bingham. A crosscut has been started on the 400 level of the Lady of the Lake; but the direction of the drift is kept secret.

PARK.—Business at the Park is booming right along. The Marsac mill will be ready to run by the 1st of the month. Work is progressing on both the railroads, the Empire mill is the new hoisting works for the Lowell mine. Next season will see it one of the liveliest camps in this West.

SIXTEEN men are employed grading and getting ready for the machinery at the Lowell & Williamson shaft, Park City. Work on the shaft commences next week. It will be a double compartment, 19 ft in diameter by 4 ft 4 inches. The plan is to sink 200 ft and then drift to the vein. Nick Treweek has the contract.

Two lots of Caledonia (Bingham) ore were sold to the Mingo Smelting Co. yesterday—one lot for \$177.50, and the other for \$24.50 per ton.

SILVER REEF ITEMS.—*Prospect*, Oct. 6: The interest in mining matters in this district is increasing daily, and certainly the outlook has never been more favorable than it is at the present time for a prosperous and busy season. Numerous properties that have been idle for the past year have either resumed operations or will do so soon. Chloriders and lessees are working in numerous instances with paying and gratifying results. In the Barbee & Walker mine prospecting is being prosecuted vigorously, and new discoveries are being made beyond a doubt that it will take several months to work the ore now in sight. Quite a number of changes have taken place since our last visit. New ore chutes have been placed at different points on the levels, and the old workings, which were at no time over safe, have been retimbered and filled with waste, so that now there is no danger of the ground giving way. The incline shaft on the Leeds mine has now shafted 45 ft. The vein continues to a considerable depth, and there is no doubt but such will be the case, the Leeds mill will be rattling away again before long. The new Buckeye shaft is being rapidly sunk, and will soon reach a depth of 150 ft. The water has not increased, and judging from the progress which is being made, and judging from the fact that the shaft is being sunk at the point at which the ore vein is expected to cut. The bullion shipment through Wells, Fargo & Co., from Silver Reef, from Oct. 1st to the 6th inclusive, aggregates \$29,974.63. The new air shaft on the Barbee & Walker mine, which has been sunk by contractors, was finished last Friday, when connection was made with the first level.

THE Evening Star Mining Co., of Leadville, Colorado, has declared a dividend of 50 cents per share, which has been payable at New York since the 5th instant.

Grasshoppers upon the Pacific Coast.

The visitations of locusts upon several different sections of the Pacific coast have brought much hardship and loss upon the agriculturists. It is true that the pests did not spread from the mountain valleys upon the great plains as it was feared they might, from the great abundance of them and the vigor of their egg-depositing last year. This threatened invasion was fortunately not realized, but there have been considerable numbers of the insects here and there in the San Joaquin and Sacramento valleys, and their presence has occasioned some damage and much alarm. This being the case we propose to give an illustrated chapter upon the destructive locusts, so that all readers may distinguish the different species, may understand their method of reproduction and recognize some of the parasites which do much in reducing their numbers. The basis of what we shall write is an article lately prepared for the *Evening Bulletin*, of this city by Prof. J. G. Lemmon, who is the thesaurus of locust learning on this coast, and for the most of the engravings which we introduce we are indebted to the courtesy of the *Bulletin* proprietors.

True locusts or grasshoppers, are insects of the straight-wing order (*Orthoptera*). They have a large head, short and stout feelers (an-

The "Leaser" (*Caloptenus atlantis*), Fig. 3, is much smaller than the others, of bright, contrasting gray and olive colors, and with a white line passing diagonally from the base of the wing down to the hind thigh.

The second genus, alluded to above, is the *cedipoda* or "big legs." This is a smaller genus of usually non-migratory and harmless locusts. But one species has, for some mysterious reason, become migratory in California to the extent of a few miles annually, and is then very destructive. This genus is without the curious spine under the neck, having a rounded Adam's apple instead, and the male abdomen is not enlarged, but tapers to a point. The principal species of the genus, the one with which we are concerned, is called the "Atrocious locust," (*Edipoda atroz*), Fig. 4.

The females are about an inch and a quarter long, of a light gray or a grayish-yellow color; the males a quarter shorter, and of a lighter yellowish or straw color. The males outnumber the females four or more to one, and are often mistaken for another species.

The "Atrocious locust" is found normally scattered all over the country, but this coast seems to be its headquarters or habitat, where the conditions favor its permanent residence and full development, and where, from Santa Barbara and Fresno to Sacramento and Shasta, loud complaints have often arisen of its swarming in immense numbers and eating the crops. The Atrocious locust (*Edipoda atroz*) is the grasshopper most frequently seen in the vicinity of the hay, and even on the streets of San

fruit trees, first devouring the leaves, then the fruit and twigs.

At Reno this season another large, green locust, over two inches long, is found following the had example of the *Caloptenus* family (to which his long neck-spine allies him) in defoliating the fruit shrubs and trees, being especially fond of roses and poplars. Also the Coral-wing grasshopper is seen trooping along with the gourmande, and the large, gray, long-winged, but harmless "Clapper locust" follows lazily after. Still another, the large, green-striped locust is too short-winged for flight at all, and wisely keeps to his eating of the umhellifer plants along the ditches, actually doing man a service by eating off the poison wild parsnip so fatal to his cattle.

The process of reproduction of the locust family is shown so well by the engravings that few words are necessary. Fig. 5, a, a, shows the female locust in different positions ovipositing; b, is the egg pod lifted out of its place in the ground and the end broken off to show the eggs; c, is a few eggs loose upon the ground; e and d, show sections of the hole in the ground, one being filled with eggs, the other being filled; f, shows an egg shell covered up. Fig. 7 shows different views of the egg mass somewhat enlarged.

Fig. 6 shows the character of the egg and the embryo as seen with the microscope. Below is the egg with its cell-like covering, which is magnified still more at one side; above is the inner shell and the young just before hatching. Fig. 8 shows in magnified form the anal char-

acteristics of the female and the organs which participate in ovipositing. The egg appears emerging from the body.

Parasites of the Locust.
One of the grandest laws in nature is that every animal, every plant, meets in time with check. Even the slowest breeding animal would soon overrun the country, were the counteracting influences by any means removed, while the more prolific species would do so in an incredible short space of time. Mother Nature, kind alike to all and cruel to all, advances her grand purposes, maintaining alive her myriads of species, each warring upon others and gaining temporary supremacy, accumulating only when in consequence of changed conditions, one species after another becomes too weak for its competitors, and is extinguished.

Something over 50 kinds of insects that prey upon the locust have been described, including wasps as large as itself, and little parasitic mites no larger than pin-heads, but which, by their great number, speedily suck the blood and soon kill their host.

DESTRUCTIVE LOCUSTS ON THE PACIFIC COAST, THEIR METHOD OF REPRODUCTION AND THE PARASITES WHICH PREY UPON THEM.

tenae), mouth furnished with strong sidewise moving jaws, and long, strong hind legs. The female abdomen terminates in four short horn-like organs arranged in pairs, one moving outward and upward, the other pair outward and downward when drilling holes in the earth for her eggs. The abdomen of the male rounds upward at the end like the prow of a boat.

Locusts are divided into many groups, comprising hundreds of genera and thousands of species differing from each other, chiefly by microscopic characters, but for the purposes of this article it is only necessary to distinguish the two genera concerned in the present California invasion.

The first genus to be considered is *Caloptenus*. The members of this large genus may be at once known by the presence of a curious spine or blunt thorn, like a yellow awl-point, which they bear under the neck, between the fore legs; also the males have the last abdominal segment greatly enlarged as well as upturned. There are 29 species in the United States, but three of which are found on the Pacific coast, the "Hated locust" (*C. spretus*), the "Red-leg" (*C. femurrubrum*), and the "Leaser" (*C. atlantis*). All of these are migratory, terribly destructive, and are known to have caused the great damage to the interior—and are suspected of aiding in the great invasion of 1838 and 1855, on the Pacific coast.

The "Hated locust" (*Caloptenus spretus*), Fig. 1, is usually one and one-quarter to one and one-half inches long, of a reddish brown color, with darker spots on body and wings. The long wings, on which it depends for its long flights of sometimes a thousand miles, extend a quarter of an inch beyond the body. The tip of the male abdomen is distinctly notched.

The "Red-leg" (*Caloptenus femurrubrum*), Fig. 2, is shorter, while of the same thickness, generally of a darker hue, while the apex of the male abdomen is truncate, as if cut squarely off.

Francisco, so he may be caught and studied by any one. Ordinarily it is harmless by its fewness in numbers, but at any season, favored by Mother Nature, it may become immensely numerous and destructive, as seen now in eastern Oregon, eastern and southern California.

Locust invasions, which occur suddenly by high-flying insects, which, when they alight, scramble about and devour every green thing, even to the bark of trees, must be some members of the long-winged, migrating *Caloptenus* family described, against which there is no remedy. The ancient Egyptian plague and the present Asiatic locusts, as also the destructive species of South America and Mexico, belong to the same great class of spine-bearers.

The Atrocious locust, which is usually few in numbers and non-migratory, has for three years past devastated Sierra valley, and last year sent colonies out to the south and west into Truckee Meadows and the valleys of Tahoe lake, Donner, and the high valleys about the railroad pass, and this year they are swarming more or less over the whole region.

What has often been noticed at the East is seen here too—all the locusts of the region go on the war-path together, at least, as far as the short wings of some of them will allow. It seems some favoring conditions of nature cause their rapid increase, and migrating and destructive eating are matters of necessity with them. So, here in all the afflicted region, locusts at some time of the year are found in vast numbers, and each devour his favorite food.

First, the "Atrocious" locust appears early in July, and attacks grain and grass on the high and dry localities, though he can, if pinched, relish rank growths of swamp grass and tule. Later comes the bright little "Leaser locust," attacking the heavier plants along the water courses and the garden vegetables. The "Red-leg" brigand lastly pounces upon the shrubs and

destructive in Sierra valley, is called the "large white grub," the larva of an insect whose full-grown form was unknown until this spring, but now known to be the larva of a "hover fly" (*Bombylius*), species not determined. The same larva has excited great interest in the interior by its effective onslaught upon the eggs of locusts. It is shown in enlarged form in Fig. 12. It seeks out a nest of eggs, eats the contents of the whole nest, 24 to 32 eggs, one by one, pushes the shells aside, while his own body, big and fat with the feast, fills the whole case, in which condition he curls up and enters upon his long winter's nap. The dormant stage lasts till spring, during which time the grub is about half an inch long and one-fifth thick, being largest in the middle and tapering slightly towards its head and tail. In this state several specimens at different times have been sent to Prof. Riley, at Washington, but he failed to perfect them in his vivarium. However, the question has been solved this spring in Sierra valley. Some earth, with an ascertained number of this larva therein, was carefully watched under glass. In July a beautiful little velvet-bodied fly, a species of *Bombylius*, appeared, having a long, black beak, with which it sucked nectar from flowers, to which it swiftly darted, then hovers above them like a hummingbird while sipping the nectar. To the services of this grub are the citizens of the north end of Sierra valley mainly indebted for untouched crops the present season, where for three years the locust has rioted, but where last fall its nests were soon emptied by this gourmand. The full-grown fly was frequently noticed in the fields about Franktown and around Reno, in August, and no doubt here, as elsewhere over the interior, this little fly is the avenging Nemesis to the locust.

The harvest throughout British Columbia has been abundant this season.

Plumas County Mining Interests.

From the *Greenville Bulletin*, a new journal started on the 29th ult. at Greenville, Plumas county, we take a resume of the mining interests of the county. The *Bulletin* starts in well by giving a good deal of local matter, and in its salutatory says: With the political contest we shall take no sides, preferring to devote our attention and energy to the advancement and upbuilding of this part of the country, and to a faithful record of its resources, capacities, possibilities and progress. Our motto will be, "Indian valley and Plumas county first, the world afterward."

The permanency and merit of the mines of the Greenville district are fully entitled to all the attention they are now receiving. The continued developments of the numerous quartz ledges now being worked are constantly attracting the attention of new capital, and the district, for gold quartz mining, promises to equal any in the State. The splendid and extensive developments of the Green Mountain mine places it among the best of the permanent producing mines of the State. The plant is extensive, and when the new 60-stamp mill, now fast approaching completion, is running, the crushing capacity, 92 stamps, will be the greatest of any mine in California. The new mill is first-class in its appointments. The cable tramway, now nearly completed, will be of capacity sufficient for all demands liable to be made on it.

The new Green Mountain mill will be ready to run in two weeks. The company have purchased the Cariboo water pipe, which they will lay across the slide on the Round Valley and Green Mountain ditch. The company have expended a large amount of money every winter repairing the ditch across the slide. The pipe will stop all further expense.

The Cherokee mine, adjoining the Green Mountain on the west, presents a very busy camp. The company have been pushing the reopening of this mine with vigor. A large amount of work has been done the past summer, and before winter the work will have so far progressed as to be unimpeded by storms.

The development on the Kettle mine shows some very rich ore. The croppings show remarkably rich ore, the ledge of which the company are now running for. The new hoisting works will have all the necessary improved machinery. The lower levels of this mine have produced very richly, and a large amount of bullion has been turned out by the old Kettle company. The development of the property is very promising. The company has just completed a fine 20-stamp water-mill.

The Plumas National mine has made some very valuable developments in their No. 3, or lower tunnel. The main pay chute of this mine is over 500 ft. in length in the No. 2 tunnel, with good ledge and pay still in the face, going west. This mine is rich in sulphurets. The company is now making extensive improvements in their mill, adding thereto seven Frue concentrators, to collect the sulphurets, and will shortly erect a furnace and chlorination works.

The No. 3 tunnel has struck the ledge within 60 ft. of the mouth of the tunnel, which from this point to No. 2 will give over 450 ft. of back on the incline of the ledge, and remarkable length on the vein. The supply of ore is years ahead of the present capacity to crush it. The Southern Eureka mine has been purchased by San Francisco and New York capital. The company have made a milling test of the ore, the results of which have been most satisfactory. A lower tunnel is being run, now in some 200 ft. They are now negotiating for a 10-stamp steam mill.

At the Gold Stripe mine a fine body of ore is being opened in the Goodwin part of the mine. The pay chute is over 140 ft. in length, and a shaft sunk on it 60 ft. There are 200 ft. of backs to this chute. The Lawrence ledge of same mine is opening out good ore. No. 3, Gold Stripe tunnel, is some 1,600 ft. in length, developing the whole mine. Two fine pay chutes of ore have been cut through. A new ledge has lately been opened, showing a fine body of quartz about 13 ft. wide, with perfect walls.

The Indian Valley mine, adjoining Greenville, gives promise of soon again being added to the list of producing mines in this district. This mine has always had the reputation of being one of the best in the county, but circumstances have prevented its being worked as its merits deserve. It has lately passed into the hands of some San Francisco gentlemen, who have been prosecuting developments that have opened out a new body of very fine grade ore, and the probabilities are the mine will be put in shape to be worked at an early date. The two mills will give a capacity of 56 stamps on this and the Union mine adjoining, part of the same property.

The Savercoo mine, near Prattville, has been sold to a syndicate representing Sacramento and New York capital, for \$35,000. The company have contracted for a 40-stamp mill, to be in running order in December. The mine gives promise of opening out big. It is rumored the Dutch Hill gravel mines are being negotiated for by some San Francisco mining men. A number of experts have been examining the property, and report well of it.

The Round Valley Reservoir Company will commence next week to clean out the entire length of their ditch. Over 2,000 ft. of 22-inch heavy iron pipe will be placed to conduct the water around the Indian Valley mine. The company will employ about 60 men, and hope to complete the work in a short time.

USEFUL INFORMATION.

PAPER BARRELS FOR OIL.—In view of the anticipated production of oil in this State, in quantities sufficient not only for home consumption but also for exportation, the following item may well be worth careful consideration: "An agent of the Standard Oil Company recently visited Hartford for the purpose of finding out whether it would be desirable to obtain of the American Paper Barrel Company of that city the enormous supply of barrels annually required by the former firm. The oil company cannot make its own wooden barrels so cheaply as it can purchase paper ones, which, if furnished at even half a cent less cost, would enable the company to save \$150 per day. The oil company own factories in Cleveland and Toledo which turn out daily 30,000 iron-bound and blue-painted wooden barrels at a cost of \$1.35 a barrel. Machines are used which put on the iron hoops at the rate of 1,200 a day, and each of these machines requires a man and two boys to attend it. Even the painting is done by machinery. If the oil company can be supplied with paper barrels at the rate of \$1.30 each, it can realize the great saving of \$9,000 a week. The American Paper Barrel Company, however, is not quite prepared to put their barrels on the market, but occasionally these barrels will undoubtedly supersede wooden ones for oil and for many other purposes."

NATURAL SPREAD OF THE APPLE TREE IN SOUTH AMERICA.—It is surprising how quickly the vegetation of many countries settled by Europeans has been modified. A writer in *Petermann's Mittheilungen* on the flora of Chile south of the Valdivia river, states that the scenery between the Rio Buena and its winding affluents reminds one very much of home. In the park-like prairies, associated with *Fagus obliqua*, a deciduous heech, are numerous scattered apple trees, originally introduced from Europe. The apple tree has spread from Valdivia to Osorno, and even crossed the Andes into northwestern Patagonia, and thence eastward. Indeed, it has become so widely spread and so general, that the Indians from the distant regions of the Argentine rivers, Rio Negro and Rio Colorado, are called manzaneros, or apple Indians. As a matter of fact, they and their kin in the provinces of Valdivia and Osorno live far more on the fruit of the apple tree than any European people, for it affords them both food and wine.

SPONTANEOUS IGNITION OF HYDROGEN.—Attention has recently been called to some peculiar cases of spontaneous ignition of hydrogen in air, the phenomenon having been noticed, it seems, in factories where quantities of zinc were being dissolved in hydrochloric acid for the preparation of zinc chloride. Violent explosions took place when no flame was near, and it was eventually ascertained that the gas took fire spontaneously. It is thought to be caused by fragments of very porous zinc, which, when lifted above the surface of the liquid, during the violent evolution of the gas, and so brought into contact with hydrogen and air, act just as spongy platinum would do under the circumstances. The performance of such operations in the open air is recommended. The ignition can be shown, according to M. Hoffman, by treating a few kilograms of finely divided zinc with acid; the zinc dust, he says, may even ignite by contact with water.

TO MAKE A STRONG PASTE.—To make a paste for fastening hills in a file hook, or for any purpose where a very strong paste is desired, the following recipe is recommended: Rice or starch paste is the best. Four parts, by weight, of fine glue are allowed to soften in 15 parts of cold water, and then moderately heated until the solution becomes quite clear; 65 parts of boiling water are now added with constant stirring. In another vessel 30 parts of starch paste are stirred up with 20 parts of cold water, so that a thin milky fluid is obtained without lumps. Into this the boiling glue solution is gradually stirred, and the whole kept at a boiling temperature for a short time. After cooling, a few drops of carbolie acid are added to the paste. This paste is exceedingly adhesive, and may be used for leather as well as for paper and cardboard. It should be preserved in corked bottles to prevent evaporation, and in this way will keep good for years.

CHEAP GAS.—Much attention has of late been directed to some new processes for producing a cheap gas by the decomposition of water, which, in the form of steam, is brought in contact with incandescent carbon. The reports made by the scientific press state that the experiments in this direction in Sweden and Russia have been attended with good results, and various scientific authorities, some of them government officials, declare that the gas has been employed for welding wrought iron, for smelting in crucibles, both pig iron and steel—the effect being very satisfactory in respect to the heating power of the gas. For illumination, this kind of gas is claimed to possess some peculiar advantages. When used for this latter purpose, the gas is conducted through a vessel filled with cotton moistened with benzine.

ADHESIVE FOR RUBBER BELTS.—A simple adhesive for rubber belts is made by sticking powdered chalk, which has been evenly sprinkled over, to the surface of the belt by cold tallow or boiled linseed oil.

A PRESERVATIVE wrapping paper, adapted for apples, oranges or other fruit, may be prepared by dipping a soft tissue paper in a bath of salicylic acid and bating it in the air to dry. The bath should consist of a strong alcoholic solution of salicylic acid diluted with all the water it will bear without precipitation. This preservative paper may be wrapped about the fruit before packing, and when the fruit arrives at its destination, the paper may be taken off and used for the same purpose again. A wrapping paper to protect furs, cloths, etc., from moth and mildew is prepared by dipping manila paper in a prepared bath, squeezing it and drying it over hot rollers. This bath consists of a mixture of 70 parts of the oil removed by the distillation of coal-tar naphtha, 5 parts of crude carbonic acid, containing at least 50% of phenola, 20 parts of thin coal tar at 160° Fahr., and 5 parts of refined petroleum.

TO PRESERVE WOODEN VESSELS.—Wooden vessels, which, especially in chemical works, are quickly destroyed, should, according to Herr Schaal be well dried in hot air, and then painted twice or thrice with a solution of paraffine in six parts of petroleum ether. Vessels in which boiling is effected with steam should further be coated with linseed-oil varnish, or with water-glass; after drying the water-glass coating should be removed by means of dilute muriatic acid. Paraffine is also well adapted for packing stuffing boxes, especially in stirring apparatus exposed to vapors of fuming and English sulphuric acid.

TO REMOVE SUNBURN AND FRECKLES.—A safe and refreshing cosmetic may be prepared for the removal of tan, sunburn and freckles. Procure at a druggist a pint bottle, exact measure, and put in one ounce of pure tincture of benzoin and fill the bottle with distilled water. This should have a fragrant, aromatic odor, and assume the color and consistency of milk. After applying with a little velvet sponge the mixture must be left to dry on, especially at night after a day's exposure to wind and sun. If the skin happens to be very sensitive and a slight burning sensation follows, more water may be added.

AMMONIA IN VEGETABLES.—H. Pellet has lately found appreciable quantities of ammonia in various kinds of grain, as well as in beet root. In wheat the weight of ammonia is one-tenth as great as that of the ashes. He thinks that ammonia and phosphoric acid enter into vegetables under the form of an ammoniacal magnesium phosphate, which is very soluble in all vegetable acids. He is now studying the effects of ammoniacal manures, and of nitrogen, under different forms, upon the amount of ammonia in vegetables.

GOOD HEALTH.

Popular Fallacies.

It is not true that sugar and candies are of themselves injurious to the teeth or the health of those who use them; so far from it, they are less injurious than any of the ordinary forms of food when employed in moderation.

Any scientific dentist will tell you that the parts of the teeth most liable to decay are those which afford lodgment to particles of food; such particles being decomposed by moisture and heat, give out an acid which will corrode steel as well as teeth; but pure sugar and pure candies are wholly dissolved, there is no remnant to be decomposed to yield this destructive acid; we remember now no item of food which is so perfectly dissolved in the mouth as sugar and candy. When visiting the sugar plantations of Cuba the attention was constantly arrested by the apparently white and solid teeth of the negroes who superintend the process of cane grinding; they drank the cane juice like water, there was no restraint as to its use, and the little urchins playing about would chew the sugar-yielding cane by the hour. It is much the same in Louisiana, where the shining faces and broad grins of the blacks are equally indicative of exuberant health and "splendid teeth."

How does it happen then that there should be "the prevalent belief" that sugar and sugar-candy destroy the teeth and undermine the health? Perhaps the most correct reply is *tradition*, the father of a progeny of errors in theory and practice; of errors in doctrine and example, "too tedious to mention."
